Thick Points for Spatial Brownian Motion:
Multifractal Analysis of Occupation Measure

Amir Dembo*  Yuval Peres†  Jay Rosen‡  Ofer Zeitouni.§

Abstract

Let $T(x,r)$ denote the total occupation measure of the ball of radius $r$ centered at $x$ for Brownian motion in $\mathbb{R}^3$. We prove that $\sup_{|x|\leq 1} T(x,r)/(r^2 \log r) \to 16/\pi^2$ a.s. as $r \to 0$, thus solving a problem posed by Taylor in 1974. Furthermore, for any $a \in (0, 16/\pi^2)$, the Hausdorff dimension of the set of “thick points” $x$ for which $\limsup_{r \to 0} T(x,r)/(r^2 \log r) = a$, is almost surely $2 - a\pi^2/8$; this is the correct scaling to obtain a nondegenerate “multifractal spectrum” for Brownian occupation measure. Analogous results hold for Brownian motion in any dimension $d > 3$. These results are related to the LIL of Ciesielski and Taylor (1962) for the Brownian occupation measure of small balls, in the same way that Lévy’s uniform modulus of continuity, and the formula of Orey and Taylor (1974) for the dimension of “fast points”, are related to the usual LIL. We also show that the lim inf scaling of $T(x,r)$ is quite different: we exhibit non-random $c_1, c_2 > 0$, such that $c_1 < \sup_x \liminf_{r \to 0} T(x,r)/r^2 < c_2$ a.s. In the course of our work we provide a general framework for obtaining lower bounds on the Hausdorff dimension of random fractals of ‘limsup type’.

1 Introduction

For any Borel measurable function \( f \) from \( 0 \leq t \leq T \) to \( \mathbb{R}^d \) we denote by \( \mu^f_t \) its occupation measure:
\[
\mu^f_t(A) = \int_0^T 1_A(f_t) \, dt
\]
for all Borel sets \( A \subseteq \mathbb{R}^d \). Throughout, \( B(x,r) \) denotes the ball in \( \mathbb{R}^d \) of radius \( r \) centered at \( x \), and \( \{W_t\}_{t \geq 0} \) denotes Brownian motion in \( \mathbb{R}^d, d \geq 3 \).

In the last decade, much insight into the structure of various measures has been gained from their multifractal analysis. A general introduction to this analysis can be found in Olsen [11], Reidi [20] and Falconer [6]; certain important random measures were analyzed by Hu-Taylor [7], Taylor [27], Perkins-Taylor [19], Lawler [10], Shieh-Taylor [23] and Jaffard [8].

Consider Brownian occupation measure \( \mu^W_t \) in \( \mathbb{R}^d, d \geq 3 \). It is well known that for almost all Brownian paths \( W \), the pointwise Hölder exponent
\[
\text{Hölder}(\mu^W_t, x) := \lim_{\epsilon \to 0} \frac{\log \mu^W_t(B(x,\epsilon))}{\log \epsilon}
\]  
(1.1)
takes the value 2 for all points \( x \) in the range \( \{W_t \mid 0 \leq t \leq T\} \). In particular, the usual multifractal spectrum \( a \mapsto \dim \{x \in \mathbb{R}^d : \text{Hölder}(\mu^W_t, x) = a\} \) vanishes for all \( a \neq 2, a > 0 \). Indeed, this fact was crucial in Kaufman’s work [9], written long before the term “multifractal” was invented.

Rather than being the end of the story, this means that standard multifractal analysis must be refined to capture the delicate fluctuations of occupation measure under scaling; the problem of obtaining such a refined analysis was posed by Hu and Taylor [7, Pg. 287] in 1997, but it is closely linked to problems posed by Taylor [25] in 1974. Our main results, Theorems 1.1 and 1.3 below, resolve these problems.

The correct scaling for studying the fluctuations of occupation measure was already indicated by Taylor [25]; more details were given by Perkins-Taylor [17, Lemmas 2.3 and 2.5], who showed that there exist absolute constants \( 0 < c_1 < c_2 < \infty \), such that almost surely for all
points $x \in \{W_t | 0 \leq t \leq T\}$ and all positive $\epsilon \leq \epsilon_0(\omega)$,

$$c_1 \epsilon^2 / |\log \epsilon| \leq \mu_T^W(B(x, \epsilon)) \leq c_2 \epsilon^2 / |\log \epsilon|. \quad (1.2)$$

(As they point out, the lower bound is immediate from Lévy’s uniform modulus of continuity.)

Our main result describes the multifractal nature, in a fine scale, of “thick points” for the occupation measure of Brownian motion in $\mathbb{R}^d$, $d \geq 3$. (We call a point $x \in \mathbb{R}^d$ on the Brownian path a thick point if $x$ is in the set considered in (1.3) for some $a > 0$; similarly, $t > 0$ is called a thick time if it is in the set $\text{Thick}_a$ considered in (1.4) for some $a > 0$ and $T > 0$.)

**Theorem 1.1** With $d \geq 3$, let $q_d$ denote the first positive zero of the Bessel function $J_{d/2-2}(x)$.

(See [30] for information on $q_d$; in particular, $q_3 = \pi/2$.) Then, for any $T \in (0, \infty]$ and all $0 < a \leq 4/q_d^2$,

$$\dim \{x \in \mathbb{R}^d \mid \limsup_{\epsilon \to 0} \frac{\mu_T^W(B(x, \epsilon))}{\epsilon^2 |\log \epsilon|} = a\} = 2 - a q_d^2 / 2 \quad \text{a.s.} \quad (1.3)$$

Equivalently, for any $T \in (0, \infty]$ and all $0 < a \leq 4/q_d^2$,

$$\dim \{0 \leq t < T \mid \limsup_{\epsilon \to 0} \frac{\mu_T^W(B(W_t, \epsilon))}{\epsilon^2 |\log \epsilon|} = a\} = 1 - a q_d^2 / 4 \quad \text{a.s.} \quad (1.4)$$

Denote the set in (1.4) by $\text{Thick}_a$. Then $\text{Thick}_a \not= \emptyset$ at the critical value $a = 4/q_d^2$.

For comparison purposes, recall three fundamental results on Brownian increments:

(i) The large increments at a fixed time $t$, are governed by Khinchin’s classical LIL:

$$\limsup_{\epsilon \to 0} \frac{W_{t+\epsilon} - W_t}{(2\epsilon |\log \epsilon|)^{1/2}} = 1 \quad \text{a.s.}$$

(ii) The dimension of certain exceptional fast points was determined by Orey-Taylor [12]:

$$\forall a \in [0, 1], \quad \dim \left\{0 \leq t < T \mid \limsup_{\epsilon \to 0} \frac{W_{t+\epsilon} - W_t}{(2\epsilon |\log \epsilon|)^{1/2}} = a\right\} = 1 - a^2 \quad \text{a.s.}$$

(This can be viewed as a multifractal decomposition of white noise.)
(iii) Lévy’s uniform modulus of continuity governs the largest increments overall:

$$\lim_{\varepsilon \to 0} \sup_{0 \leq t \leq T} \frac{W_{t+\varepsilon} - W_t}{(2\varepsilon |\log \varepsilon|)^{1/2}} = 1 \text{ a.s.}$$

The three statements above hold in any dimension $d \geq 1$. Next, we indicate their analogues for Brownian occupation measure in dimension $d \geq 3$; only the first of these was previously known.

(i’) The limsup asymptotic behavior of Brownian occupation measure around a fixed time $t$, is governed by the LIL of Ciesielski-Taylor [3, Theorem 3]: for any $T \in (0, \infty]$ and $t \leq T$,

$$\limsup_{\varepsilon \to 0} \frac{\mu^W_T(B(W_t, \varepsilon))}{\varepsilon^2 \log |\log \varepsilon|} = \frac{2}{d^2} \text{ a.s.}$$

(1.5)

(ii’) The dimension of exceptional thick times is given by (1.4) above.

(iii’) Our results (1.7) and (1.9) give the largest occupation measure possible for a small ball.

Further remarks on Theorem 1.1.

- Perhaps more significant than the numerical values obtained in (1.3) and (1.4) is the insight gained, while proving these results, about the manner by which the “thick points” on the Brownian path arise. The key to our proof of Theorem 1.1 is a localization phenomenon for transient Brownian motion: the balls of radius $\varepsilon$ that have the largest occupation measure (of order $\varepsilon^2 |\log \varepsilon|$), accumulate most of this measure in a surprisingly short time interval (of length at most $\varepsilon^2 |\log \varepsilon|^{b'}$ for some $b$, e.g. $b = 6$ works); see Section 3 where this localization is established. The localization phenomenon breaks down in dimension $d = 2$, where the correct scaling of occupation measure, and the techniques needed to establish it, are quite different. We have obtained the corresponding results for the planar case, and will present them separately; we emphasize that the current paper concerns only $d \geq 3$.

- Given the localization phenomenon, there are several possible approaches to the proof of the lower bound in (1.4). Our proof relies on a general lower bound on Hausdorff
measure of random fractals “of limsup type”, Theorem 2.1. This general bound sharpens similar estimates obtained by Orey-Taylor [12], Hu-Taylor [7], Deheuvels-Mason [4] and Shieh-Taylor [23]; of course, our work owes a substantial debt to these earlier papers.

- For any $x \notin \{ W_t \mid 0 \leq t \leq T \}$ and $\epsilon$ small enough, $\mu^W_t(B(x, \epsilon)) = 0$. Hence, the equivalence of (1.3) and (1.4) is a direct consequence of the uniform dimension doubling property of Brownian motion, due to Kaufman [9] (see also, [17, Eqn. (0.1)]).

- Let $\Lambda_d^{-1}$ denote the first eigenvalue of the (Dirichlet) half-Laplacian in the unit ball of $\mathbb{R}^{d-2}$. As the spherically symmetric fundamental solution for the Laplacian eigenvalue problem in $B(0, 1)$ is $J_{d/2-2}(\sqrt{\lambda}|x|)$, the required Dirichlet boundary conditions imply that $\Lambda_d^{-1} = q_d^2/2$ (see for example [3, (2.15)]). The appearance of $(d - 2)$ here is due to the celebrated identity of Ciesielski-Taylor [3, Theorem 2].

To indicate the qualitative difference between the sets of thick points and the most familiar random fractals associated with Brownian motion (the range, the graph, and the level sets) we present the following proposition; for the definition and properties of packing dimension $\text{dim}_p$, see [28] or [6].

**Proposition 1.2** Let the notation of Theorem 1.1 be in force. For all $0 < a < 4/q_d^2$, the union $\text{Thick}_{\geq a} := \cup_{b \geq a} \text{Thick}_b$ has the same Hausdorff dimension as $\text{Thick}_a$ a.s., but its packing dimension a.s. satisfies $\text{dim}_p(\text{Thick}_{\geq a}) = 1$. Equivalently,

$$\text{dim}_p\{ x \in \mathbb{R}^d \mid \limsup_{\epsilon \to 0} \frac{\mu^W_t(B(x, \epsilon))}{e^2|\log \epsilon|} \geq a \} = 2 \quad \text{a.s.} \quad (1.6)$$

**Remark.** The importance of comparing the Hausdorff and packing dimensions of a set was stressed in the survey Taylor [26]. By a more involved argument, it can be shown that $\text{Thick}_a$ itself also has packing dimension 1 for $0 < a \leq 4/q_d^2$.

The next theorem solves two problems posed by Taylor in 1974 (see [25, Pg. 201]).
**Theorem 1.3** Let \( \{W_t\} \) be a Brownian motion in \( \mathbb{R}^d, \ d \geq 3 \). Then, for any \( R \in (0, \infty) \) and any \( T \in (0, \infty) \),
\[
\lim_{\epsilon \to 0} \sup_{|x| \leq R} \frac{\mu^W_T(B(x, \epsilon))}{\epsilon^2 |\log \epsilon|} = 4q_d^{-2} \quad \text{a.s.} \tag{1.7}
\]
Furthermore, for any \( k \in (0, \infty) \) and any \( T \in [k, \infty) \),
\[
\lim_{\epsilon \to 0} \inf_{t \in [0, k]} \frac{\mu^W_T(B(W_t, \epsilon))}{\epsilon^2 |\log \epsilon|} = 1 \quad \text{a.s.} \tag{1.8}
\]

**Remarks:**

- Our proof shows that for any \( T \in (0, \infty) \),
\[
\lim_{\epsilon \to 0} \sup_{0 \leq t \leq T} \frac{\mu^W_T(B(W_t, \epsilon))}{\epsilon^2 |\log \epsilon|} = 4q_d^{-2} \quad \text{a.s.} \tag{1.9}
\]
- Combining (1.3) and (1.7) we see that
\[
\sup_{x \in \mathbb{R}^d} \lim_{\epsilon \to 0} \sup_{0 \leq t \leq T} \frac{\mu^W_T(B(x, \epsilon))}{\epsilon^2 |\log \epsilon|} = 4q_d^{-2} \quad \text{a.s.}
\]

In particular, the sets in (1.3) and (1.4) are a.s. empty for any \( a > 4q_d^{-2} \), \( T \in (0, \infty] \).

Computation of Laplace transforms is an important component of a complete multifractal analysis, and it was also the starting point of our investigation. Pemantle, Peres and Shapiro [14] showed that \( \int_0^1 \mu^W_1(B(W_t, \epsilon))/\epsilon^2 \ dt \), the pathwise first moment of the ratio \( \mu^W_1(B(W_t, \epsilon))/\epsilon^2 \), remains bounded almost surely as \( \epsilon \to 0 \). The following theorem provides a pathwise asymptotic formula for the moment generating function of that ratio. In one sense, it is finer than Theorem 1.1, since it yields a precise estimate of the total duration in \([0, 1]\) that the Brownian particle spends in balls of radius \( \epsilon \) that have unusually high occupation measure (see Corollary 1.5 below). Such an estimate (which is an analogue in our setting of the “coarse multifractal spectrum”, cf. Reidi [20]), cannot be inferred from Theorem 1.1.

**Theorem 1.4** Denote by \( \tilde{\mu}^W_\infty \) the total occupation measure for a two-sided Brownian motion \( \{\tilde{W}_t\}_\infty \) in \( \mathbb{R}^d, \ d \geq 3 \). Then for each \( \theta < q_d^2/2 \),
\[
\lim_{\epsilon \to 0} \int_0^1 e^{\theta \mu^W_1(B(W_t, \epsilon))/\epsilon^2} \ dt = \mathbb{E}\left(e^{\theta \tilde{\mu}^W_\infty(B(0, 1))}\right) \quad \text{a.s.} \tag{1.10}
\]
Remarks:

- We note by [3] that

\[
\mathbb{E} \left( e^{\theta \rho_{\infty}^W (B(0,1))} \right) = \left( \mathbb{E} \left( e^{\theta \rho_{\infty}^W (B(0,1))} \right) \right)^2 = \prod_{j=1}^{\infty} \left( 1 - \frac{2\theta}{q_{d,j}} \right)^2
\]

for each \( \theta < q_d^2/2 \), where \( \{q_{d,j}\}_{j \geq 1} \) are the positive zeros of the Bessel function \( J_{d/2-2}(x) \), enumerated in increasing order. It is clear that the right hand side diverges as \( \theta \uparrow q_d^2/2 = q_{d,1}^2/2 \). The case \( d = 3 \) is particularly explicit because then \( q_3 = \pi/2 \) and the right hand side of (1.11) simplifies to \( \cos^{-2}(\sqrt{2\theta}) \) (c.f. [3]).

- Let \( \tau \) denote a random variable uniform on \([0,1]\), which is independent of the Brownian path \( W \). Then, (1.10) implies in particular that for almost every Brownian path \( W \), the ratio \( \mu^W_1 (B(W_t, \epsilon)) / \epsilon^2 \), a random variable in \( \tau \), converges in law as \( \epsilon \to 0 \) to the total occupation time \( \overline{\mu}^W (B(0,1)) \) of the unit ball by a two-sided Brownian motion \( \tilde{W} \).

Next, we state the promised corollary of Theorem 1.4, which is analogous to the coarse multifractal spectrum.

**Corollary 1.5** Let \( \{W_t\} \) be a Brownian motion in \( \mathbb{R}^d \), \( d \geq 3 \), and denote Lebesgue measure on \( \mathbb{R}^1 \) by \( \text{Leb} \). Then, for any \( a \in (0, 4/q_d^2) \),

\[
\lim_{\epsilon \to 0} \frac{\log \mathbb{E} \left\{ 0 \leq t \leq 1 \left| \epsilon \mu^W_1 (B(W_t, \epsilon)) \geq a \epsilon^2 \log \epsilon \right. \right\}}{\log \epsilon} = a q_d^2 / 2 \quad \text{a.s.}
\]

The thick points considered in Theorem 1.1 are centers of balls \( B(x, \epsilon) \) with unusually large occupation measure for infinitely many radii, but these radii might be quite rare. The next theorem shows that for the balls \( B(x, \epsilon) \) to have unusually large occupation measure for \textit{all} small radii \( \epsilon \) and the same center \( x \), what constitutes “unusually large” must be interpreted more modestly. Define

\[
I_d(a) := \frac{a}{4} (\max\{0, d - 2 - \frac{2}{a}\})^2,
\]

(1.12)
and let
\[ C_d := \inf \{ a : I_d(a) = 2 \} = \frac{2}{d - 2\sqrt{d} - 1}. \]  
(1.13)
(The equality on the right is easily verified.)

Then

**Theorem 1.6** For \( \{W_t\} \) a Brownian motion in \( \mathbb{R}^d \), \( d \geq 3 \), and \( a \in (0, C_d] \),
\[ \dim \{ x \in \mathbb{R}^d \mid \liminf_{\epsilon \to 0} \frac{\mu^W(B(x, \epsilon))}{\epsilon^2} \geq a \} \leq 2 - I_d(a) \quad \text{a.s.} \]  
(1.14)
and this can be strengthened to
\[ \dim_p \{ x \in \mathbb{R}^d \mid \liminf_{\epsilon \to 0} \frac{\mu^W(B(x, \epsilon))}{\epsilon^2} \geq a \} \leq 2 - I_d(a) \quad \text{a.s.} \]  
(1.15)
where \( \dim_p \) denotes packing dimension. Moreover,
\[ \frac{1}{d} \leq \sup_{x \in \mathbb{R}^d} \liminf_{\epsilon \to 0} \frac{\mu^W(B(x, \epsilon))}{\epsilon^2} \leq C_d \quad \text{a.s.} \]  
(1.16)

**Remarks:**

- In particular, replacing the lim sup by lim inf in (1.3) and (1.4) yields an a.s. empty set for any \( a > 0 \).
- The new assertion in (1.16) is the right hand inequality; the inequality on the left is an immediate consequence of Theorem 9 of Perkins [16] concerning “Brownian slow points”.
- It is an open problem to determine exactly the dimension appearing in (1.14) and the precise asymptotics in (1.16).
- That the upper bound (1.14) on Hausdorff dimension applies to packing dimension as well is in sharp contrast with Theorem 1.1 and Proposition 1.2. Intuitively, the reason for this contrast is that for a point to be in the set considered in (1.3), it only needs to satisfy a certain condition at infinitely many scales, so that set can appear large at other scales; these scales can be used to pack many disjoint balls with centers in the set. Points considered in (1.14), however, must satisfy a (less stringent) condition at all scales.
The next section contains a discussion of fractals “of limsup type” and a general lower bound (Theorem 2.1) for their Hausdorff measure. In Section 3 we prove the crucial Localization Lemma 3.1. The results of those two sections are applied in Section 4 to establish the lower bounds on Hausdorff dimension in Theorem 1.1 and Proposition 1.2. The complementary upper bounds in Theorem 1.1 are proved in Section 5. Combining these bounds with the Localization Lemma 3.1, we prove Theorem 1.3 in Section 6. Section 7 is devoted to the proof of Theorem 1.4, with Corollary 1.5 proved in Section 8. Theorem 1.6 is proved in Section 9. At the end of the paper we present some open problems.

Analogous results for transient symmetric stable processes will appear in [5].

2 Random fractals of limsup type

Suppose that for each $n \geq 1$, a finite union $A(n)$ of intervals of length $\lambda_n$ is given. Assume that $\lambda_n \to 0$ as $n \to \infty$, and that the number of intervals comprising $A(n)$ grows like a negative power of $\lambda_n$. We call $A := \limsup A(n) = \bigcap_{n=1}^{\infty} \bigcup_{k=n}^{\infty} A(k)$ a fractal of limsup type. We will be interested in situations in which the $A(n)$ are random, and in hypotheses on their distribution which will allow us to obtain dimension bounds on $A$. The main result of this section, Theorem 2.1, provides a general framework for obtaining lower bounds on the Hausdorff measure of random fractals of limsup type.

Random sets that are (well approximated by) random fractals of limsup type include:

- The fast points of Orey-Taylor [12];
- The initial points of exceptional Brownian excursions considered by Barlow-Perkins [1];
- The close approaches on the Brownian path measured by Perkins-Taylor [18];
- The paths in a family tree where a tree-indexed random walk has positive burst speed, see Benjamini-Peres [2];
- Times where the Strassen functional LIL fails, see Deheuvels-Mason [4];
• Sets arising in multifractal analysis of stable subordinators (studied by Hu-Taylor [7] and by Shieh-Taylor [23]).

• The sets $\text{Thick}_\alpha$ in Theorem 1.1.

Such random sets differ qualitatively from the random fractals most frequently encountered (e.g. ranges, graphs, levels sets and slow points of Brownian motion). For instance, the packing dimension of sets of limsup type is typically full, hence larger than their Hausdorff dimension; see Corollary 2.4. In particular, that corollary implies that the sets of fast points of [12] have packing dimension 1 (The assertion to the contrary in [26, Pg. 401] is wrong).

Three general methods have been employed to establish lower bounds for Hausdorff dimension of random fractals of limsup type. (These methods were used earlier for other sets).

• Orey-Taylor [12] constructed a Frostman measure directly, using estimates on binomial probabilities. Their method is expounded by Deheuvels-Mason [4]. This elegant method requires strong independence assumptions “within levels”, and it is difficult to refine it to handle sets defined by an equality, like $\text{Thick}_\alpha$, rather than an inequality. Orey-Taylor [12, Pg. 185] state that this can be done for the random fractals of limsup type which they consider, the Brownian fast points, by “tightening their argument”, but extending this to more general situations seems quite hard.

• Intersection properties with an independent random set (the range of a stable subordinator) were used by Barlow-Perkins [1] and Perkins-Taylor [18]; random Cantor sets arising from fractal percolation as in [15] could also be used. Here independence assumptions can be replaced by correlation bounds, but, as above, handling sets like $\text{Thick}_\alpha$ is unwieldy.

• A powerful method based on estimation of energy integrals was used by Hu-Taylor [7] and Shieh-Taylor [23]. Below we sharpen and extend this method, and show that it yields good estimates of Hausdorff measure, while requiring only mild correlation hypothesis.

Let $\mathcal{D}_n$ denote the collection of dyadic intervals $\{[(i - 1)2^{-n}, i2^{-n}]\}_{i=1}^{2^n}$. For any increasing
function $\varphi : [0, 1] \to [0, \infty)$ with $\varphi(0) = 0$, let $\mathcal{H}^\varphi(A)$ denote the Hausdorff measure of a set $A$ in the gauge $\varphi$ (see, e.g., [26] for the definition).

**Theorem 2.1** Suppose that for every $n \geq 1$, a collection of $\{0, 1\}$ valued random variables $\{Z_I\}_{I \in \mathcal{D}_n}$ is given, so that $p_n := \mathbf{P}(Z_I = 1)$ is the same for all $I \in \mathcal{D}_n$. Let

$$A(n) = \bigcup \{I \in \mathcal{D}_n \mid Z_I = 1\} \text{ and } A := \limsup_{n \to \infty} A(n) = \bigcap_{n=1}^{\infty} \bigcup_{k=n}^{\infty} A(k).$$

For $I \in \mathcal{D}_m$, with $m < n$, define

$$M_n(I) = \sum_{J \in \mathcal{D}_n, J \subseteq I} Z_J.$$

Choose $\zeta(n) \geq 1$ such that

$$\text{Var}(M_n(I)) \leq \zeta(n) \mathbf{E}(M_n(I)) = \zeta(n)p_n 2^{n-m}. \quad (2.1)$$

Let $\varphi(r)$ be a gauge function which is regularly varying of index $\alpha \in (0, 1) \text{ as } r \downarrow 0$. (I.e.,

$$\varphi(r) = r^\alpha L(r) \text{ where } L(br)/L(r) \to 1 \text{ as } r \downarrow 0 \text{ for any } c > 0.$$  

If

$$\frac{2^{-n} \zeta(n)}{\varphi(2^{-n}) p_n} \to 0 \quad (2.2)$$

then $\mathcal{H}^\varphi(A) > 0 \text{ a.s.}$

**Remarks:**

- We emphasize that no independence or correlation assumptions are made relating $Z_I$ and $Z_J$ for $I$ and $J$ of different lengths.
- $\mathcal{H}^\varphi(A) > 0$ immediately implies that $\dim(A) \geq \alpha$.
- Theorem 2.1 can be applied to the “fast points” and “thick points” of a variety of processes; the only essential requirements are stationarity of increments, suitable decay of correlations and (for discontinuous processes) bounds on the jump probabilities. The non-vanishing of Hausdorff measure is proved in Theorem 2.1, rather than merely a

11
bound on dimension, in order to handle the sets $\text{Thick}_a$, rather than just their unions $\text{Thick}_{\geq a} = \cup_{b \geq a} \text{Thick}_b$, in (1.4). (See the remark following the statement of Corollary 4.1).

- Let $\varphi_n := 1/\varphi(2^{-n})$. Beyond the obvious fact of some exponential growth of $\varphi_n$, our proof uses only the following simple consequence of the assumption that $\varphi(r)$ is regularly varying of index $\alpha \in (0, 1)$ as $r \downarrow 0$: for some $C < \infty$ that does not depend on $n$,

\[ \sum_{m=1}^{n} \varphi_m \leq C \varphi_n \quad \text{and} \quad \sum_{m=n}^{\infty} 2^{-m} \varphi_m \leq C 2^{-n} \varphi_n. \quad (2.3) \]

- We will apply Theorem 2.1 below to prove Theorem 1.1. In that application, we will take $\varphi(r) = r^{1-\gamma} |\log_2 (r)|^{13}$ with $p_n \geq 2^{-n\gamma}$ for some $0 < \gamma < 1$ and $\zeta(n) = n^{12}$, where throughout this paper, $\log_2$ stands for the logarithm to the base 2.

- Theorem 2.1, which is formulated for random fractals of limsup type in $[0, 1]$, has an obvious generalization to random 'fractals of limsup type' in $[0, 1]^d$. In this setup we can take $\varphi(r)$ to be any gauge function which is regularly varying of index $\alpha \in (0, d)$ as $r \downarrow 0$, and replace (2.1) and (2.2) by $\text{Var}(M_n(I)) \leq \zeta(n) \mathbb{E}(M_n(I)) = \zeta(n)p_n 2^{d(n-m)}$ and $2^{-dn} \zeta(n)/\varphi(2^{-n})p_n \to 0$ respectively. The proof of such a generalization is basically identical to the proof of Theorem 2.1.

To establish Theorem 2.1 we need two lemmas. The first one is a version of the well-known connection between energy and Hausdorff measure. For the reader's convenience, we include the brief proof.

**Lemma 2.2** Fix an increasing gauge function $\varphi$ such that $\varphi(0) = 0$. Suppose that $B$ is a Borel set in $[0, 1]$, and $\nu$ is a probability measure on $B$. If the dyadic energy

\[ \mathcal{E}_\varphi(\nu) := \sum_{m=1}^{\infty} \sum_{J \in \mathcal{D}_m} \frac{\nu(J)^2}{\varphi(2^{-m})} \]

of $\nu$ is finite, then $\mathcal{H}^\varphi(B) > 0$. 

12
(In fact $\mathcal{H}^\varphi(B) = \infty$, but that is unimportant for our purpose). See [13] for the connection of $\mathcal{E}_\varphi(\nu)$ to more traditional expressions for energy.

**Proof:** Let

$$\Psi(x) := \sum_{m=1}^\infty \sum_{J \in \mathcal{D}_m} \frac{\nu(J)}{\varphi(2^{-m})} 1_J(x).$$

Since $\int_B \Psi(x) \, d\nu = \mathcal{E}_\varphi(\nu)$, taking $C = 2\mathcal{E}_\varphi(\nu)$, the set $B_C := \{ x \in B \mid \Psi(x) \leq C \}$ has $\nu(B_C) \geq 1/2$. The restriction $\nu_C$ of $\nu$ to $B_C$ satisfies $\nu_C(J) \leq C\varphi(2^{-m})$ for every $J \in \mathcal{D}_m$ for all $m$. Since any interval $I \subset [0, 1]$ can be covered by three shorter dyadic intervals, it follows that $\nu_C(I) \leq 3C\varphi(|I|)$ for any interval $I$. Hence, if $\mathcal{A}$ is any countable collection of intervals with $B_C \subseteq \bigcup_{\mathcal{A}} I$, then

$$\frac{1}{2} \leq \nu(B_C) \leq \sum_{\mathcal{A}} \nu_C(I) \leq 3C \sum_{\mathcal{A}} \varphi(|I|)$$

which implies that $1/(6C) \leq \mathcal{H}^\varphi(B_C)$.

Alternatively, the a.s. finiteness of $\Psi$, in conjunction with [22], imply that $\mathcal{H}^\varphi(B) = \infty$. □

The following lemma, which, roughly speaking, controls the “quadratic variation” of the random sets $A(n)$, is the key to the proof of Theorem 2.1. Recall that $\varphi_n = 1/\varphi(2^{-n})$, and note that by (2.2), for any $\ell$ we can choose an integer $n(\ell) > \ell$ such that

$$\frac{\varphi(n(\ell))}{2^{n(\ell)p_n(\ell)}} \leq 2^{-3\ell}. \quad (2.4)$$

**Lemma 2.3** Let the assumptions of Theorem 2.1 be in force. There exist an a.s. finite random variable $\ell_0(\omega)$ and a constant $C_3$, such that if $\ell \geq \ell_0(\omega)$ and $n = n(\ell)$, then for all $D \in \mathcal{D}_\ell$, we have

$$|M_n(D) - \mathbb{E}M_n(D)| < \frac{1}{2} \mathbb{E}M_n(D), \quad (2.5)$$

and

$$\sum_{m=\ell}^{n(\ell)} \varphi_m \sum_{J \in \mathcal{D}_m, J \subset D} \frac{M_n(J)^2}{(2^{-n}\ell p_n(\ell))^2} \leq C_3 \varphi_\ell. \quad (2.6)$$

**Proof:** For $m \leq n$ and $J \in \mathcal{D}_m$, denote

$$\Delta_n(J) := M_n(J) - \mathbb{E}M_n(J).$$

13
Also, for \( \ell \leq n \) and \( D \in \mathcal{D}_t \), set
\[
\gamma_n(D) := \sum_{m=\ell}^{n} \varphi_m \sum_{J \in \mathcal{D}_m, J \subset D} \Delta_n(J)^2.
\]
For \( J \in \mathcal{D}_m \), the assumption (2.1) gives \( \mathbf{E}[\Delta_n(J)^2] \leq \zeta(n)p_n2^{n-m} \). Therefore,
\[
\forall D \in \mathcal{D}_t, \quad \mathbf{E}\gamma_n(D) = \sum_{m=\ell}^{n} \varphi_m 2^{m-\ell} \zeta(n)p_n2^{n-m} = 2^{n-\ell} \zeta(n)p_n \sum_{m=\ell}^{n} \varphi_m.
\]
By (2.3), we then have
\[
\mathbf{E}\gamma_n(D) \leq C2^{n-\ell}p_n^2\varphi_n\zeta(n)/p_n.
\]
Thus, by (2.4), since \( n = n(\ell) \),
\[
\mathbf{E}\sum_{D \in \mathcal{D}_t} \frac{\gamma_n(D)}{(2^{n-\ell}p_n)^2} \leq C2^{-\ell}.
\]
Since the right-hand side is summable in \( \ell \), we conclude that the summands inside the last expectation tend to 0 a.s. as \( \ell \to \infty \). In particular, there exists \( \ell_0(\omega) < \infty \) such that for all \( \ell \geq \ell_0(\omega) \) and \( D \in \mathcal{D}_t \), we have
\[
\gamma_n(D) \leq (2^{n-\ell}p_n)^2 = [\mathbf{E}\varphi_m(D)]^2.
\]
To deduce (2.5), observe that
\[
\Delta_n(D)^2 \leq \varphi^{-1}_\ell \gamma_n(D) \leq \varphi^{-1}_\ell [\mathbf{E}\varphi_m(D)]^2 \leq \frac{1}{4}[\mathbf{E}\varphi_m(D)]^2.
\]
Next, we calculate
\[
\sum_{J \in \mathcal{D}_m, J \subset D} \frac{[\mathbf{E}\varphi_m(J)]^2}{(2^{n-\ell}p_n)^2} = \sum_{J \in \mathcal{D}_m, J \subset D} 2^{2(\ell-m)} = 2^{\ell-m}.
\]
Therefore, by (2.3),
\[
\sum_{m=\ell}^{n} \varphi_m \sum_{J \in \mathcal{D}_m, J \subset D} \frac{[\mathbf{E}\varphi_m(J)]^2}{(2^{n-\ell}p_n)^2} = 2^{\ell} \sum_{m=\ell}^{n} 2^{-m} \varphi_m \leq C\varphi_\ell.
\]
Rewrite (2.7) in the form
\[
\sum_{m=\ell}^{n} \varphi_{m} \sum_{J \in \mathcal{D}_{m}, J \subset D} \frac{\Delta_{n}(J)^{2}}{(2n-\ell p_{n})^{2}} = \frac{1}{(2n-\ell p_{n})^{2}} \sum_{m=\ell}^{n} \varphi_{m} \sum_{J \in \mathcal{D}_{m}, J \subset D} \Delta_{n}(J)^{2} \leq 1. \tag{2.9}
\]
Since
\[M_{n}(J)^{2} = [\mathbb{E}M_{n}(J) + \Delta_{n}(J)]^{2} \leq 2[\mathbb{E}M_{n}(J)]^{2} + 2\Delta_{n}(J)^{2},\]
adding the inequalities (2.8) and (2.9) yields (2.6), for a suitable constant \(C_{3}\).
\[\square\]

**Proof of Theorem 2.1.** We use freely the terminology introduced in the statement of Lemma 2.3. With \(\ell_{0} = \ell_{0}(\omega)\) as in the lemma, define inductively \(\ell_{k+1} := n(\ell_{k})\) for \(k \geq 0\). For \(D \in \mathcal{D}_{\ell_{k-1}}\) with \(k \geq 1\), write
\[Q_{k} := \mathbb{E}M_{\ell_{k}}(D) = 2^{\ell_{k}-\ell_{k-1}}p_{\ell_{k}},\]
and note that by (2.5),
\[\forall k \geq 1 \ \forall D \in \mathcal{D}_{\ell_{k-1}}, \quad \frac{1}{2}Q_{k} \leq M_{\ell_{k}}(D) \leq 2Q_{k}. \tag{2.10}\]
Summing this over \(D \in \mathcal{D}_{\ell_{k-1}}\) gives
\[\forall k \geq 1 \quad M_{\ell_{k}}([0,1]) \leq 2^{\ell_{k-1}+1}Q_{k}. \tag{2.11}\]

To establish the theorem, we will construct a (random) probability measure \(\nu\), supported on \(\cap_{k \geq 1} A(\ell_{k}) \subset A\), such that \(\mathcal{E}_{\nu}(\nu) < \infty\) a.s. To specify \(\nu\), it suffices to define \(\nu(J)\) consistently for all binary intervals \(J\). Start by assigning the leftmost interval in \(\mathcal{D}_{\ell_{0}}\) full measure, i.e., set \(\nu[0,2^{-\ell_{0}}] := 1\). Continue inductively:

If \(J \in \mathcal{D}_{m}\) with \(\ell_{k-1} < m \leq \ell_{k}\), and \(J \subset D\) with \(D \in \mathcal{D}_{\ell_{k-1}}\), define
\[\nu(J) := \frac{M_{\ell_{k}}(J)\nu(D)}{M_{\ell_{k}}(D)}. \tag{2.12}\]

It is straightforward to verify that this assignment is consistent and that \(\nu\) is supported on \(\cap_{k \geq 1} A(\ell_{k})\). For \(k \geq 2\) and \(J\) as in (2.12), two applications of (2.10) and the bound
\[\nu(D) \leq \frac{Z_{D}}{\min_{D \in \mathcal{D}_{\ell_{k-2}}} M_{\ell_{k-1}}(D)},\]

15
give
\[
\nu(J) \leq \frac{2M_{t_k}(J)\nu(D)}{Q_k} \leq \frac{4M_{t_k}(J)Z_D}{Q_kQ_{k-1}}. \tag{2.13}
\]
Now we apply Lemma 2.3. For \( k \geq 2 \) and \( D \in \mathcal{D}_{t_{k-1}} \),
\[
\sum_{m=t_{k-1}}^{t_k} \varphi_m \sum_{J \in \mathcal{D}_m, J \subset D} \nu(J)^2 \leq \frac{16Z_D}{Q^2_{k-1}} \sum_{m=t_{k-1}}^{t_k} \varphi_m \sum_{J \in \mathcal{D}_m, J \subset D} \frac{M_{t_k}(J)^2}{Q^2_k} \leq \frac{16C_2Z_D}{Q^2_{k-1}} \varphi_{t_{k-1}}, \tag{2.14}
\]
by the definition of \( Q_k \) and (2.6). Summing this over all \( D \in \mathcal{D}_{t_{k-1}} \), and then using (2.11) with \( k - 1 \) in place of \( k \), we obtain
\[
\sum_{m=t_{k-1}}^{t_k} \varphi_m \sum_{J \in \mathcal{D}_m} \nu(J)^2 \leq \frac{16C_2^2M_{t_{k-1}}([0,1])}{Q^2_{k-1}} \varphi_{t_{k-1}} \leq \frac{C_42^{t_{k-2}}}{Q^2_{k-1}} \varphi_{t_{k-1}} \leq \frac{C_42^{t_{k-2}}}{Q^2_{k-1}} \varphi_{t_{k-1}} \leq C_42^{-t_{k-2}}, \tag{2.15}
\]
where the last step used (2.4) and the fact that \( \zeta \geq 1 \). As the right-hand side of (2.15) is summable in \( k \), we conclude that
\[
\mathcal{E}_\varphi(\nu) = \sum_{m=0}^{\infty} \varphi_m \sum_{J \in \mathcal{D}_m} \nu(J)^2 < \infty \quad \text{a.s.}
\]
By Lemma 2.2, this completes the proof. \( \square \)

The next corollary will be used to prove Proposition 1.2 in Section 4. If \( K \subset [0,1] \), then we write \( \mathcal{N}_m(K) \) for the number of intervals in \( \mathcal{D}_m \) that intersect \( K \).

The only property of the packing dimension \( \dim_p \) we need, is that if a closed set \( K \subset [0,1] \) satisfies
\[
\limsup_{m \to \infty} \frac{\log_2 \mathcal{N}_m(K \cap V)}{m} \geq \eta \tag{2.16}
\]
for any open set \( V \) that intersects \( K \), then \( \dim_p(K) \geq \eta \). See Tricot [29] or Falconer [6, Prop. 3.6].

**Corollary 2.4** In the setting of Theorem 2.1, the random set \( A = \lim \sup A(n) \) satisfies \( \dim_p(A) = 1 \) a.s.
Proof: Using the notation of Theorem 2.1 and Chebycheff’s inequality, we have for \( m < n \) and \( J \in \mathcal{D}_m \) that

\[
P[M_n(J) = 0] \leq \frac{\text{Var}M_n(J)}{[\mathbb{E}M_n(J)]^2} \leq \frac{\zeta(n)}{2^{n-m}p_n} \leq \frac{\zeta(n)\varphi_n}{2^n p_n} \leq \frac{2^m}{\varphi_n},
\]

where the last step used (2.2) with \( n \) sufficiently large. The assumption that \( \varphi \) is regularly varying of index \( \alpha > 0 \) certainly implies that \( \varphi_n \geq 2^{an/2} \) for large \( n \). Therefore, if \( m \) is large enough and \( n > 8m/\alpha \), then

\[
\sum_{J \in \mathcal{D}_m} P[M_n(J) = 0] \leq 2^{-an/4},
\]

and consequently

\[
\sum_m \sum_{n>8m/\alpha} \sum_{J \in \mathcal{D}_m} P[M_n(J) = 0] < \infty.
\]

The Borel-Cantelli Lemma then implies that almost surely, for all sufficiently large \( m \),

\[
\forall n > 8m/\alpha, \quad \forall J \in \mathcal{D}_m, \quad M_n(J) > 0. \tag{2.17}
\]

To complete the proof, we will use the notation introduced in the proof of Theorem 2.1, and show that the compact set \( A^* := \bigcap_{k \geq 1} A(\ell_k) \) satisfies \( \dim_p(A^*) = 1 \) a.s. (note that \( A^* \neq \emptyset \) by our proof of Theorem 2.1). Without loss of generality we can assume that \( \ell_{k+1} > 8\ell_k^2/\alpha \) for all \( k \).

Fix an open set \( V \) that intersects \( A^* \). For all sufficiently large \( k \), there is an interval \( I(k) \in \mathcal{D}_{t_k} \) actually contained in the intersection of \( V \) with \( \bigcap_{j=1}^k A(\ell_j) \). Hence, if \( \mathcal{I} := \{ J \in \mathcal{D}_{t_k} : J \subseteq I(k) \} \), each interval \( J \in \mathcal{I} \) is also contained in the intersection of \( V \) with \( \bigcap_{j=1}^k A(\ell_j) \). We now show that in fact each \( J \in \mathcal{I} \) has non-empty intersection with \( A^* := \bigcap_{k \geq 1} A(\ell_k) \). By applying (2.17) with \( m = \ell_k^2 \) and \( n = \ell_{k+1} \), we deduce that every interval \( J \in \mathcal{I} \) contains an interval \( J_{k+1} \in A(\ell_{k+1}) \). Then, from (2.17) it follows that every interval \( J \in \mathcal{I} \) contains an infinite nested sequence of intervals \( J_r \in A(\ell_r) \), \( r \geq k + 1 \), hence has non-empty intersection with \( A^* := \bigcap_{k \geq 1} A(\ell_k) \) as claimed. Since \( |\mathcal{I}| = 2^{\ell_k^2-\ell_k} \) we have that \( \mathcal{N}_{\ell_k^2}(A^* \cap V) \geq 2^{\ell_k^2-\ell_k} \) for all large \( k \), and this implies that \( \dim_p(A^*) = 1 \) a.s. by the criterion in (2.16). \( \square \)
3 Localization

Throughout this section, $c$, $c'$ denote positive, finite constants, independent of $\epsilon$, the values of which may change from line to line, using the notation $a \sim b$ if $\lim_{\epsilon \to 0} a/b = 1$.

To derive lower bounds on the Hausdorff dimension of the sets appearing in Theorem 1.1, as well as for proving (1.7), it is crucial to be able to consider the occupation measure of a ball of radius $\epsilon$ over a small time interval (of length $\delta_\epsilon$ which tends to zero with $\epsilon$), rather than over an interval of constant length.

Surprisingly, it turns out that with only a small loss in probability, we can work with rather short time intervals; the following lemma makes this precise.

Lemma 3.1 (The Localization Lemma) Let $\{W_t\}$ be a Brownian motion in $\mathbb{R}^d$, $d \geq 3$. Write $h(r) := r^2 \log r$, and $\theta^* := \Lambda_d^{-1} = d^2/2$. Finally, denote $\delta_\epsilon := \epsilon^2 |\log \epsilon|^6$ and $\beta_\epsilon := 1 - 2|\log \epsilon|^{-2}$. Then for some $0 < c < \infty$, we have

$$p_\epsilon := \mathbb{P}(h_{\delta_\epsilon}^W (B(0, \epsilon \beta_\epsilon)) \geq ah(\epsilon)) \geq c e^{o_{\theta^*}} .$$

We did not attempt to optimize the powers of $|\log \epsilon|$ appearing in the definitions of $\delta_\epsilon$ and $\beta_\epsilon$. Nevertheless, to appreciate the sharpness of this lemma, recall that by [3], c.f. (3.4) below,

$$\mathbb{P}(h_{\infty}^W (B(0, \epsilon)) \geq ah(\epsilon)) \sim c' e^{o_{\theta^*}} .$$

Proof: Define

$$\mathcal{T} = \mathcal{T}(\epsilon) := \inf\{s \geq 0 : |W_s| = \epsilon |\log \epsilon|^2\} .$$

By Brownian scaling, we deduce the existence of positive constants $c_1, c_2$ such that

$$\mathbb{P}(\mathcal{T} > \delta_\epsilon) = \mathbb{P}\left( \sup_{t \in [0, |\log \epsilon|^2]} |W_t| \leq 1 \right) \sim c_1 \exp(-c_2 |\log \epsilon|^2) . \quad (3.1)$$

Therefore,

$$p_\epsilon \geq \mathbb{P}(\epsilon^{-2} \int_0^T 1_{\{|W_s| < \epsilon \beta_\epsilon\}} ds \geq a |\log \epsilon|; \mathcal{T} \leq \delta_\epsilon) \geq \mathbb{P}(\epsilon^{-2} \int_0^T 1_{\{|W_s| < \epsilon \beta_\epsilon\}} ds \geq a |\log \epsilon|) - \mathbb{P}(\mathcal{T} > \delta_\epsilon) \quad (3.2)$$

18
By (3.1) and (3.2), the lemma will be proved once we establish that
\[
P(e^{-2} \int_{0}^{T} 1_{\{|W_{s}|<\beta_{s}\}} ds \geq a|\log \epsilon|) \geq ce^{\alpha^*}.
\] (3.3)

To see (3.3), denote by \(\tau_{d-2}\) the hitting time of the unit sphere in \(\mathbb{R}^{d-2}\) by Brownian motion, and define
\[
I = e^{-2} \int_{0}^{\infty} 1_{\{|W_{s}|<\beta_{s}\}} ds,
\]
\[
I^{T} = e^{-2} \int_{0}^{T} 1_{\{|W_{s}|<\beta_{s}\}} ds.
\]
Recall that, using [3] for the first equality,
\[
\frac{P(\int_{0}^{\infty} 1_{\{|W_{s}|<1\}} ds \geq x)}{e^{-\theta x}} = \frac{P(\tau_{d-2} \geq x)}{e^{-\theta x}} \rightarrow_{x \rightarrow \infty} c.
\] (3.4)

Therefore, using Brownian scaling and (3.4),
\[
P(I \geq a|\log \epsilon|) = P((\beta_{c}\epsilon)^{-2} \int_{0}^{\infty} 1_{\{|W_{s}|<\beta_{s}\}} ds \geq \beta_{c}^{-2}a|\log \epsilon|)
= P(\tau_{d-2} \geq \beta_{c}^{-2}a|\log \epsilon|)
\sim c \exp \left( -\theta^* a |\log \epsilon|/(1-2|\log \epsilon|^{-2}) \right) \sim ce^{\alpha^*}.
\] (3.5)

Let now \(T := \inf\{t > \mathcal{T} : |W_{t}| < \epsilon\}\), and define
\[
I_{T'} = e^{-2} \int_{T'}^{\infty} 1_{\{|W_{s}|<\beta_{s}\}} ds.
\]
Then, \(I = I^{T} 1_{\{T'=\infty\}} + (I^{T} + I_{T'}) 1_{\{T'<\infty\}}\) so that
\[
P(I^{T} \geq z; T' = \infty) = P(I \geq z) - P(I^{T} + I_{T'} \geq z; T' < \infty).
\] (3.6)

Let \(\bar{I}\) be an independent copy of \(I\) for a Brownian motion whose expectation when starting at \(v\) we denote by \(\mathbb{E}^{v}\). Using symmetry and the strong Markov property we have
\[
P(I^{T} + I_{T'} \geq z; T' < \infty) = \mathbb{E} \left( \mathbb{E}^{\mathbb{W}_{T'}} \{ \bar{I} \geq z - I^{T} \} ; T' < \infty \right)
\leq \mathbb{E} \left( \mathbb{E} \{ \bar{I} \geq z - I^{T} \} ; T' < \infty \right)
= \mathbb{E} \left( \mathbb{E} \{ I^{T} \geq z - \bar{I} ; T' < \infty \} \right)
= \mathbb{E} \left( \mathbb{E} \{ \mathbb{E}^{\mathbb{W}_{T}} (T_{B(0,v)} < \infty) ; I^{T} \geq z - \bar{I} \} \right)
= \left| \log \epsilon \right|^{-2(d-2)} \mathbb{P}(I^{T} + \bar{I} \geq z)
\leq \left| \log \epsilon \right|^{-2(d-2)} \mathbb{P}(I + \bar{I} \geq z)
\] (3.7)
where $T_{B(0, \epsilon)} = \inf \{t \geq 0 : W_t \in B(0, \epsilon) \}$ denotes the first hitting time of $B(0, \epsilon)$.

Let $\tilde{\tau}_{d-2}$ denote an independent copy of $\tau_{d-2}$, and let $q_r$ denote their common law. Then, for some constant $C$ independent of $\epsilon$, which may change from line to line,

$$
P(\tau_{d-2} + \tilde{\tau}_{d-2} > z) = P(\tau_{d-2} > z) + \int_0^z \exp(-s \theta^*) dy \exp(0, \epsilon) P(\tilde{\tau}_{d-2} > z - y) q_r(dy)
$$

$$
\leq C \left[ \exp(-z \theta^*) + \int_0^z \exp(-s \theta^*) q_r(dy) \right]
$$

$$
\leq C \exp(-z \theta^*) + C \int_0^z \exp(-s \theta^*) dy
$$

$$
= C(1 + z) \exp(-z \theta^*),
$$

(3.8)

where the third line came from integration by parts. Hence, by the same argument as in (3.5), for some $c > 0$ and any $\epsilon > 0$ small enough,

$$
P(I + \tilde{I} \geq a | \log \epsilon| \leq c a | \log \epsilon| \epsilon^{\theta^*}.
$$

Since $2(d - 2) > 1$, the inequality (3.3) follows from (3.5), (3.6), (3.7) and the above. \qed

4 Proof of the lower bound and critical case in Theorem 1.1

The following corollary of Theorem 2.1 and the Localization Lemma will yield the desired lower bound. From its proof we will also obtain Proposition 1.2 concerning packing dimension.

Recall that $\theta^* = \Lambda_d^{-1} = a_d^2/2$ denotes the first eigenvalue of the Dirichlet half-Laplacian in the unit ball of $\mathbb{R}^{d-2}$.

**Corollary 4.1** Let $T \in (0, \infty]$ and $a \in (0, 2 \Lambda_d)$. Denote $h(\epsilon) = e^2 | \log \epsilon |$, and consider the set of “thick times”

$$
\text{Thick}_{\geq a} = \{ 0 \leq t < T \mid \limsup_{\epsilon \to 0} \frac{\mu W(B(W_t, \epsilon))}{h(\epsilon)} \geq a \}. \nonumber
$$

Let $\gamma = a \theta^*/2 \in (0, 1)$ and $\varphi(r) = r^{1-\gamma} | \log r |^{13}$. Then $\mathcal{H}^{\varphi}(\text{Thick}_{\geq a}) > 0$ a.s.

20
Derivation of the lower bound in Theorem 1.1: Assuming for the moment the upper bounds on dimension obtained in Section 5, we may infer that \( \dim(\text{Thick}_a) = 1 - \gamma \) as follows (cf. the argument in [12, Pg. 185]). The inequality \( \dim(\text{Thick}_{\gamma(a+1/n)}) \leq 1 - (a + 1/n)\theta^*/2 \) of Section 5 implies that \( \mathcal{H}^\theta(\text{Thick}_{\gamma(a+1/n)}) = 0 \), and since \( \text{Thick}_a = \text{Thick}_{\gamma a} \cup \bigcup_{n=1}^{\infty} \text{Thick}_{\gamma(a+1/n)} \), Corollary 4.1 shows that \( \mathcal{H}^\theta(\text{Thick}_a) > 0 \) which in turn implies that \( \dim(\text{Thick}_a) \geq 1 - \gamma \). Using once again the upper bound from Section 5 then completes the proof that \( \dim(\text{Thick}_a) = 1 - \gamma \).

\[ \square \]

Derivation of the critical case in Theorem 1.1: We now show that \( \text{Thick}_{4/q_d^2} \neq \emptyset \); perhaps surprisingly, this can be done by a “soft” argument. For \( h > 0 \) and \( a < 4/q_d^2 \), consider the set of approximate thick times

\[
\text{Thick}(a, h) := \bigcup_{\epsilon \in (0, h)} \left\{ 0 < t < T \left| \frac{\mu_t^W(B(W_1, \epsilon))}{\epsilon^2 |\log \epsilon|} > a \right. \right\}.
\]

For any \( a < 4/q_d^2 \) and \( h > 0 \), it follows from (1.4) and the Markov property of Brownian motion, that \( \text{Thick}(a, h) \) is a.s. dense in \([0, T]\), and it is easy to check that \( \text{Thick}(a, h) \) is an open set. Thus fixing sequences \( a_n \uparrow 4/q_d^2 \) and \( h_n \downarrow 0 \), Baire’s category theorem implies that

\[
\cap_n \text{Thick}(a_n, h_n) \neq \emptyset.
\]

Finally, inspection shows that this intersection coincides with \( \text{Thick}_{\geq 4/q_d^2} \), which in turn coincides with \( \text{Thick}_{4/q_d^2} \) by the remark following Theorem 1.3.

\[ \square \]

Proof of Corollary 4.1: Since we are proving a lower bound, we may assume that \( T \) is finite; by Brownian scaling, it is enough to prove the lemma for \( T = 2 \). Take \( \epsilon_n = n^{32^{-n}/2} \), \( n = 1, 2, \ldots \) and \( \beta_n = 1 - 2|\log \epsilon_n|^{-2} \) as in the Localization Lemma. With \( I = [t, t + 2^{-n}] \in \mathcal{D}_n \), define \( \tilde{I} = [t, t + n^{122^{-n}}] \), and let

\[
Z_I = 1 \quad \text{iff} \quad \int_I 1_{\{|W_s - W_t| < \epsilon_n \beta_n\}} ds \geq ah(\epsilon_n).
\]

By Lévy’s uniform modulus of continuity, there exists an a.s. finite random variable \( n_0(\omega) \), such that for all \( n \geq n_0(\omega) \),

\[
\sup \{|W_t - W_{t'}| : t, t' \in [0, 1], |t - t'| \leq 2^{-n}\} \leq 2\sqrt{2^{-n} \log(2n)}.
\]

21
Therefore, for all $n > n_0(\omega)$, if $I \in \mathcal{D}_n$ and $Z_I = 1$, then $\int_{I} 1_{|W_{t'} - W_t| < \varepsilon_n} ds \geq ah(\varepsilon_n)$ for every $t' \in I$. The set $A$ defined in Theorem 2.1 satisfies $A \subset \text{Thick}_{\geq a}$ a.s. (we have taken $T = 2$ rather than $T = 1$ to avoid boundary effects here). The Localization Lemma, Lemma 3.1, shows that for $I \in \mathcal{D}_n$, and all $n$ large enough, $p_n = \mathbb{P}(Z_I = 1) \geq 2^{-dn/2}$. Thus, Corollary 4.1 will be established once we verify the variance condition (2.1). For intervals $I, J \in \mathcal{D}_n$ the variables $Z_I$ and $Z_J$ always satisfy $\text{Cov}(Z_I, Z_J) \leq \mathbb{E}(Z_I) = p_n$, and if $\text{dist}(I, J) > n^{12}2^{-n}$, then $Z_I$ and $Z_J$ are independent. Therefore, fixing $m < n$ and $D \in \mathcal{D}_m$, each $I \in \mathcal{D}_n$ satisfies $\text{Cov}(Z_I, M_n(D)) \leq n^{12}p_n$. Consequently

$$\text{Var}(M_n(D)) = \sum_{I \in \mathcal{D}_n, I \subset D} \text{Cov}(Z_I, M_n(D)) \leq 2^{n-m}n^{12}p_n.$$ 

Hence, Theorem 2.1 may be applied (with $p_n \geq 2^{-\gamma n}$ and $\zeta(n) = n^{12}$) to yield the conclusion.

\[\square\]

**Proof of Proposition 1.2:** In the course of the proof of Corollary 4.1, we showed that for $a \in (0, 2\Lambda_d)$, the set $\text{Thick}_{\geq a}$ contains a set of the form $A = \limsup A(n)$ that satisfies the hypothesis of Theorem 2.1. Thus, the assertion $\dim_p(\text{Thick}_{\geq a}) = 1$ follows immediately from Corollary 2.4. Finally, we may deduce (1.6) from the uniform doubling of packing dimension by spatial Brownian motion, established by Perkins-Taylor [17, Cor. 5.8].

\[\square\]

## 5 The upper bound in Theorem 1.1

In this section we establish the upper bound for (1.3), thus completing the proof of Theorem 1.1.

Let $\{W_t\}_{t \geq 0}$ be a Brownian motion in $\mathbb{R}^d$, $d \geq 3$, and $h(\varepsilon) = \varepsilon^2 |\log \varepsilon|$. Set

$$z_T(x, \varepsilon) := \mu_T^W(B(x, \varepsilon))/h(\varepsilon),$$

with $z(x, \varepsilon) = z_{\infty}(x, \varepsilon)$. In this section we show that

$$\dim\{x \in B(0, k) \mid \limsup_{\varepsilon \to 0} z(x, \varepsilon) \geq a \} \leq 2 - a\Lambda_d^{-1}$$

(5.1)
a.s. for all $a \leq 2\Lambda_d$, $k \in [1, \infty)$. Using $z(x, \epsilon) \geq z_T(x, \epsilon)$, and considering the countable union over $k = 1, 2, \ldots$, will then complete the proof of the upper bound on the dimension of sets in (1.3).

Fix $k \in [1, \infty)$ and $\delta \in (0, 1/5)$. Choose a sequence $\epsilon_n \downarrow 0$ as $n \to \infty$ in such a way that $\epsilon_1 < \epsilon^{-2}$ and

$$h(\epsilon_{n+1}) = (1 - \delta)h(\epsilon_n). \tag{5.2}$$

Since, for $\epsilon_{n+1} \leq \epsilon \leq \epsilon_n$ we have

$$z(x, \epsilon_n) = \frac{h(\epsilon_{n+1})}{h(\epsilon_n)} \frac{\mu^W(\mathbb{B}(x, \epsilon_n))}{h(\epsilon_{n+1})} \geq (1 - \delta)z(x, \epsilon) \tag{5.3}$$

it is easy to see that for any $a > 0$,

$$\{x \in B(0, k) \mid \limsup_{\epsilon \to 0} z(x, \epsilon) \geq a\} \subset D_a := \{x \in B(0, k) \mid \limsup_{n \to \infty} z(x, \epsilon_n) \geq (1 - \delta)a\}.$$

Let $\{x_j : j = 0, 1, \ldots, K_n\}$, with $x_0 = 0$, denote a maximal collection of points in $B(0, k)$ such that $\inf_{t \neq j} |x_t - x_j| \geq \delta \epsilon_n$. Let $\mathcal{A}_n$ be the set of $j$, $0 \leq j \leq K_n$, such that

$$\mu^W(\mathbb{B}(x_j, (1 + \delta)\epsilon_n)) \geq (1 - 2\delta)ah(\epsilon_n).$$

We will shortly prove that for any $a > 0$,

$$\mathbb{E}|\mathcal{A}_n| \leq c \epsilon^{(1 - 4\delta)a \theta^* - 2}. \tag{5.4}$$

Assuming this for the moment, fix $a \leq 2/\theta^*$ and let $\mathcal{V}_{n,j} = \mathbb{B}(x_j, \delta \epsilon_n)$. For any $x \in B(0, k)$ there exists $j \in \{0, \ldots, K_n\}$ such that $x \in \mathcal{V}_{n,j}$ and $\mathbb{B}(x, \epsilon_n) \subset \mathbb{B}(x_j, (1 + \delta)\epsilon_n)$. Consequently, $\cup_{n \geq m} \cup_{j \in \mathcal{A}_n} \mathcal{V}_{n,j}$ forms a cover of $D_a$ by sets of maximal diameter $2\delta \epsilon_m$. Since $\mathcal{V}_{n,j}$ have diameter $2\delta \epsilon_n$, it follows from (5.4) that for $\gamma = 2 - (1 - 5\delta)a \theta^* > 0$,

$$\mathbb{E} \sum_{n=m}^{\infty} \sum_{j \in \mathcal{A}_n} |\mathcal{V}_{n,j}|^\gamma \leq c \epsilon^{(2\delta)\gamma} \sum_{n=m}^{\infty} \epsilon_n^{\delta a \theta^*} < \infty.$$

Thus, $\sum_{n=m}^{\infty} \sum_{j \in \mathcal{A}_n} |\mathcal{V}_{n,j}|^\gamma$ is finite a.s. implying that $\dim(D_a) \leq \gamma$ a.s. Taking $\delta \downarrow 0$ completes the proof of the upper bound (5.1), subject only to (5.4) which we now prove.
Let \( \sigma_j = \inf\{ t \geq 0 : W_t \in B(x_j, (1 + \delta)\epsilon_n) \} \). By the strong Markov property, and \([3] \) (c.f. (3.4)), for some \( c = c(\delta, a, d) < \infty \) and all \( n \)

\[
P(\mu^W_\infty(B(x_j, (1 + \delta)\epsilon_n)) \geq (1 - 2\delta)a h(\epsilon_n)) \\
= P(\mathcal{W}_{\sigma_j} (\mu^W_\infty(B(0, (1 + \delta)\epsilon_n)) \geq (1 - 2\delta)a h(\epsilon_n)))) ; \sigma_j < \infty) \\
\leq P(\mathcal{E} (\mu^W_\infty(B(0, (1 + \delta)\epsilon_n)) \geq (1 - 2\delta)a h(\epsilon_n))) ; \sigma_j < \infty) \\
\leq c \epsilon_n^{(1-4\delta)\alpha^*} P(\sigma_j < \infty)
\]

where the first inequality is due to symmetry. Recall that

\[
P(\sigma_j < \infty) = \left( \frac{(1 + \delta)\epsilon_n}{|x_j|} \right)^{d-2} \wedge 1.
\]

Hence, for some \( c_1 = c_1(\delta, a, d) \), \( c' = c(\delta, a, d, k) < \infty \) and every \( n \),

\[
\mathbb{E} |A_n| = \sum_{j=0}^{K_n} P(\mu^W_\infty(B(x_j, (1 + \delta)\epsilon_n)) \geq (1 - 2\delta)a h(\epsilon_n)) \\
\leq c_1 \epsilon_n^{(1-4\delta)\alpha^*} - (1 + \int_{|x| \leq k} \frac{1}{|x|^{d-2}} dx) \leq c' \epsilon_n^{(1-4\delta)\alpha^*} - 2
\]

which completes the proof of (5.4) and consequently the proof of Theorem 1.1. \( \square \)

6 Solution of Taylor’s 1974 problems

Proof of Theorem 1.2: We begin by proving (1.7). To this end, fix \( T \in (0, \infty) \), \( \delta \in (0, 1/4) \) and \( a < 2\lambda_d = 2/\theta^* \) such that \( \eta = 2 - (1 + \delta) a \theta^* > 0 \). Choose a sequence \( \epsilon_n \downarrow 0 \) as in (5.2), noting that for \( \epsilon_n \leq \epsilon \leq \epsilon_{n-1} \) and any \( x \in \mathbb{R}^d \),

\[
(1 - \delta) z_T(x, \epsilon_n) \leq z_T(x, \epsilon) \leq (1 - \delta)^{-1} z_T(x, \epsilon_{n-1}).
\]

Let \( \delta_\epsilon = \epsilon^2 | \log \epsilon |^6, N_n = [T/\delta_\epsilon], \) and \( t_{i,n} = i\delta_\epsilon \) for \( i = 0, \ldots, N_n - 1 \). Writing \( W_t = W_t - W_0 \) it follows that

\[
\inf_{\epsilon \in [\epsilon_n, \epsilon_{n-1}]} \sup_{t \in [0, T]} z_T(W_t, \epsilon) \geq (1 - \delta) \max_{i=0}^{N_n-1} z_T^{(n)}(i),
\]

24
where \( Z_i^{(n)} = \mu_{\delta_n}^{W^1, n}(B(0, \epsilon_n))/h(\epsilon_n) \) are i.i.d. and by Lemma 3.1, for some \( c = c(T) > 0 \) and all \( n \) large enough,
\[
P\left( \max_{i=0}^{N_n-1} Z_i^{(n)} \leq a \right) \leq (1 - p_{\epsilon_n})^{N_n} \leq e^{-c\epsilon_n^{-n}}.
\]
Since \( \epsilon_n^n \) is summable, applying Borel-Cantelli, then taking \( \delta \downarrow 0 \) and \( a \uparrow 2\Lambda_d \), we see that a.s.
\[
\liminf_{\epsilon \to 0} \sup_{t \in [0, T]} z_T(W_t, \epsilon) \geq 2\Lambda_d = 4q_d^{-2}
\]
With \( S_k(\omega) = \inf\{t : |W_t| \geq k\} \land T \in (0, \infty) \) a.s. and \( T \mapsto z_T(x, r) \) monotone non-decreasing, it follows that a.s.
\[
\liminf_{\epsilon \to 0} \sup_{|x| \leq k} z_T(x, \epsilon) \geq \liminf_{\epsilon \to 0} \sup_{t \in [0, S_k(\omega)]} z_{S_k(\omega)}(W_t, \epsilon) \geq 4q_d^{-2}.
\]

Turning to the proof of the corresponding upper bound, fix \( k \in (0, \infty), \delta \in (0, 1/5) \) and let \( a = (2 + \delta)/(1 - 4\delta) > 2/\theta^* \). Considering the sequence \( \epsilon_n \) of (5.2) and the sets \( A_n \) as in Section 5, it follows from (5.4) that
\[
\sum_{n=1}^{\infty} P(|A_n| \geq 1) \leq \sum_{n=1}^{\infty} E|A_n| \leq c' \sum_{n=1}^{\infty} \epsilon_n^\delta < \infty
\]
By Borel-Cantelli, it thus follows that a.s. \( A_n \) is empty for all \( n \geq n_0(\omega) \). By the construction of Section 5 the latter event implies that
\[
\limsup_{\epsilon \to 0} \sup_{|x| \leq k} z_\infty(x, \epsilon) \leq a.
\]
Taking \( \delta \downarrow 0 \) for which \( a \downarrow 2/\theta^* = 4q_d^{-2} \), we conclude that a.s.
\[
\limsup_{\epsilon \to 0} \sup_{|x| \leq k} z_\infty(x, \epsilon) \leq 4q_d^{-2},
\]
as needed to complete the proof of (1.7).

The left side of (1.8) is monotone in \( T \) and by Brownian scaling its law depends only on \( T/k \). Therefore, it suffices to consider \( k = 1 \) and the extreme values \( T = 1 \) and \( T = \infty \). Fix \( \delta > 0 \) and \( \epsilon_n = (1 - \delta)^n \). (Note, this is different from the \( \epsilon_n \) used above!). Using the notation
\[
\hat{z}_T(x, \epsilon) := \frac{\mu_T^W(B(x, \epsilon))}{(e^2/|\log \epsilon|)},
\]
25
it follows that for any $\epsilon \in [\epsilon_n, \epsilon_{n-1}]$ and $x \in \mathbb{R}^d$

$$\frac{n-1}{n}(1-\delta)^2 \hat{z}_T(x, \epsilon_n) \leq \hat{z}_T(x, \epsilon) \leq \frac{n}{n-1}(1-\delta)^{-2} \hat{z}_T(x, \epsilon_{n-1}) .$$

Thus, it suffices for (1.8) to show that for any fixed $\delta \in (0, 1/5)$ both the lower bound

$$\liminf_{n \to \infty} \inf_{t \in [0,1]} \hat{z}_1(W_t, \epsilon_n) \geq (1-\delta)^5$$

(6.2)

and the upper bound

$$\limsup_{n \to \infty} \inf_{t \in [0,1]} \hat{z}_\infty(W_t, \epsilon_n) \leq (1+\delta)^5,$$

(6.3)

hold a.s.

Our first task in proving (6.2) is to get a good upper bound on the probability of small occupation measure. If $\mu_{[-a,b]}^W(B(0,\epsilon_n))$ denotes the occupation measure of a two-sided $\mathbb{R}^d$-valued Brownian motion $\hat{W}$ in $B(0,\epsilon_n)$ during the time interval $[-a,b]$ with $a,b \geq 0$, then

$$\mu_{[-a,b]}^W(B(0,\epsilon_n)) \leq \gamma$$

implies that $\bar{\tau}_d(\epsilon_n) \wedge a + \tau_d(\epsilon_n) \wedge b \leq \gamma$, where

$$\bar{\tau}_d(\epsilon) = \inf\{t \geq 0 : |\hat{W}_{-t}| \geq \epsilon\}, \quad \tau_d(\epsilon) = \inf\{t \geq 0 : |\hat{W}_t| \geq \epsilon\}.$$ 

Taking $\gamma = (1-\delta)^2 \epsilon_n^2/|\log \epsilon_n|$, then $a \wedge b \geq (1-\delta)^2 \epsilon_n^2/|\log \epsilon_n|$ together with Brownian scaling shows that

$$\mathbf{P}\left(\mu_{[-a,b]}^W(B(0,\epsilon_n)) \leq (1-\delta)^2 \epsilon_n^2/|\log \epsilon_n|\right) \leq \mathbf{P}\left(\bar{\tau}_d(1) + \tau_d(1) \leq (1-\delta)^2/|\log \epsilon_n|\right).$$

(6.4)

Since $\mathbf{P}(\tau_d(1) \leq x) = \mathbf{P}(\sup_{0 \leq t \leq x} |W_t| \geq 1)$, it is well known, see [28, Lemma 6.4], that for $0 < x < 1$

$$c_1 x^{1-d/2} e^{-5x} \leq \mathbf{P}(\tau_d(1) \leq x) \leq c_2 x^{1-d/2} e^{-5x}.$$

(6.5)

This estimate leads, as in the proof of [28, Lemma 6.5], to

$$\mathbf{P}(\bar{\tau}_d(1) + \tau_d(1) \leq x) \leq e^{-2(1-\delta)/x}$$

(6.6)

for any $\delta > 0$ and $x \leq x(\delta)$. Hence, whenever $a \wedge b \geq (1-\delta)^2 \epsilon_n^2/|\log \epsilon_n|$,

$$\mathbf{P}\left(\mu_{[-a,b]}^W(B(0,\epsilon_n)) \leq (1-\delta)^2 \epsilon_n^2/|\log \epsilon_n|\right) \leq \epsilon_n^{2/(1-\delta)}$$

(6.7)
for all $n \geq n_0(\delta)$, which is the good upper bound we need. In particular, using $\tilde{W}_t^f = \tilde{W}_{t+s} - \tilde{W}_t$ for the time-shifted path, this shows that for all $n \geq n_0(\delta),$

$$\mathbf{P}(\hat{z}_1(W_t, \epsilon_n) \leq (1 - \delta)^2) = \mathbf{P}(\mu_{|t-t_{i-1}|}^W[0, \epsilon_n]) \leq (1 - \delta)^2 \epsilon_n^2 / |\log \epsilon_n| \leq \epsilon_n^2/(1-\delta)$$

(6.8)

provided that

$$(1 - \delta)^2 \epsilon_n^2 / |\log \epsilon_n| \leq t \leq 1 - (1 - \delta)^2 \epsilon_n^2 / |\log \epsilon_n|$$

(6.9)

On the other hand, if $0 \leq t \leq 1$ but condition (6.9) does not hold, (i.e. for $t$ close to 0 or 1), we can no longer use the good upper bound (6.8), but must work with the following bound which comes from (6.5):

$$\mathbf{P}(\hat{z}_1(W_t, \epsilon_n) \leq (1 - \delta)^2) \leq \mathbf{P}(\tau(1, 1 - \delta)^2 / |\log \epsilon_n|) \leq \epsilon_n^{-5/(1-\delta)}$$

(6.10)

for all $n \geq n_1(\delta)$, some $n_1(\delta) < \infty$.

To apply these estimates for proving (6.2) take $k = k(\delta) = 20(1 - \delta)^2/\delta^2$ to be an integer, $\rho_n = (1 - \delta)^2 \epsilon_n^2 / (|\log \epsilon_n| k(\delta)) = \delta^2 \epsilon_n^2 / (20|\log \epsilon_n|)$, $N_n = \lfloor \rho_n^{-1} \rfloor$ and $t_{i,n} = i \rho_n$, $i = 1, \ldots, N_n$.

On the one hand, by Lévy’s uniform modulus of continuity, we have that a.s. for some finite $n_0 = n_0(\omega) \geq \delta^{-1}$ and all $n \geq n_0$,

$$\max_{i=1}^{N_n} \sup_{|s| < \rho_n} |W_{t_{i,n} + s} - W_{t_{i,n}}| < \delta \epsilon_{n-1} ,$$

which implies that

$$\inf_{t \in [0,1]} \hat{z}_1(W_t, \epsilon_{n-1}) \geq (1 - \delta)^3 \min_{i=1}^{N_n} \hat{z}_1(W_{t_{i,n}}, \epsilon_n).$$

(6.11)

On the other hand, we see that condition (6.9) is satisfied by all but the first and last $k$ points of the form $t = t_{i,n}$, $i = 1, \ldots, N_n$. Hence, using the good upper bound (6.8) for those $t_{i,n}$, and the bound (6.10) for the remaining $2k$ $t_{i,n}$’s we have

$$\mathbf{P}(\min_{i=1}^{N_n} \hat{z}_1(W_{t_{i,n}}, \epsilon_n) \leq (1 - \delta)^2) \leq \sum_{i=1}^{N_n} \mathbf{P}(\hat{z}_1(W_{t_{i,n}}, \epsilon_n) \leq (1 - \delta)^2) \leq 2k \epsilon_n^{-5/(1-\delta)} + N_n \epsilon_n^2/(1-\delta) \leq \epsilon_n^{2\delta}.$$ 

(6.12)

Since $\epsilon_n^{2\delta}$ is summable, combining (6.11) and (6.12) yields (6.2) by an application of the Borel-Cantelli Lemma.
Turning to prove (6.3), let now \( \gamma_n = (1 + \delta)^5 \epsilon_n^2 / (2 \log \epsilon_n) \), \( \rho_n = \epsilon_n^{2-5.6\delta} \) and \( n \) large enough for \( \rho_n \geq \gamma_n \). (Our choice of the constant 5.6 will become clear at the end of the proof). Consider the event \( \mathcal{A} = \mathcal{A}^+ \cap \mathcal{A}^- \), where

\[
\mathcal{A}^+ = \{ \tau_d((1 + \delta)\epsilon_n) \leq \gamma_n, \quad \inf_{s \in [0, \rho_n]} |W_{\tau_d((1 + \delta)\epsilon_n)} + s| \geq \epsilon_n, \quad |W_{\tau_d((1 + \delta)\epsilon_n) + \rho_n}| \geq \epsilon_n^{1-\delta} \}
\]

and

\[
\mathcal{A}^- = \{ \tau_d((1 + \delta)\epsilon_n) \leq \gamma_n, \quad \inf_{s \in [0, \rho_n]} |W_{-\tau_d((1 + \delta)\epsilon_n)} - s| \geq \epsilon_n, \quad |W_{-\tau_d((1 + \delta)\epsilon_n) - \rho_n}| \geq \epsilon_n^{1-\delta} \}.
\]

By the strong Markov property and symmetry,

\[
P(\mathcal{A}^+) = P\left[P^{W_{\tau_d((1 + \delta)\epsilon_n)}} \left( |W_{\rho_n}| \geq \epsilon_n^{1-\delta}, \quad \inf_{s \in [0, \rho_n]} |W_s| \geq \epsilon_n \right); \tau_d((1 + \delta)\epsilon_n) \leq \gamma_n \right]
\]

\[
= P(\tau_d((1 + \delta)\epsilon_n) \leq \gamma_n) P^{x_0} \left( |W_{\rho_n}| \geq \epsilon_n^{1-\delta}, \quad \inf_{s \in [0, \rho_n]} |W_s| \geq \epsilon_n \right), \quad (6.13)
\]

for any \( x_0 \) with \( |x_0| = (1 + \delta)\epsilon_n \).

By Brownian scaling, \( P(\tau_d((1 + \delta)\epsilon_n) \leq \gamma_n) = P(\tau_d(1) \leq (1 + \delta)^3 / (2 |\log \epsilon_n|)) \), so that using (6.5) and \( (1 + \delta)^{-3} = 1 - 3\delta + O(\delta^2) \) we get

\[
c_3 \epsilon_n^{1-2.9\delta} \leq P(\tau_d((1 + \delta)\epsilon_n) \leq \gamma_n) \leq c_4 \epsilon_n^{1-3.1\delta}
\]

for some \( c_3, c_4 > 0, \delta \text{ small and all } n \text{ large enough. Since} \)

\[
P^{x_0} \left( \inf_{s \leq 0} |W_s| < \epsilon \right) = \left( \frac{\epsilon}{|x|} \right)^{d-2}, \quad (6.14)
\]

whenever \( |x| > \epsilon \), we have, with \( |x_0| = (1 + \delta)\epsilon_n \),

\[
P^{x_0} \left( \inf_{s \leq 0} |W_s| \geq \epsilon_n \right) = 1 - (1 + \delta)^{-(d-2)} \quad (6.15)
\]

hence

\[
1 - (1 + \delta)^{-(d-2)} \leq P^{x_0} \left( \inf_{s \in [0, \rho_n]} |W_s| \geq \epsilon_n \right) \leq 1, \quad (6.16)
\]

28
while
\[
P^{x_0}\left(|W_{\rho_n}| \leq \epsilon_n^{1-\delta}\right) = P\left(|x_0 + \epsilon_n^{1-2.8\delta}W_1| \leq \epsilon_n^{1-\delta}\right) = P\left(|\epsilon_n^{2.8\delta}(x_0/\epsilon_n) + W_1| \leq \epsilon_n^{1.8\delta}\right) \to 0
\]

since \(|x_0/\epsilon_n| = 1 + \delta\), independent of \(n\). Putting this all together and noting that \(P(A) = P(A^+)P(A^-) = P(A^+)^2\) shows that
\[
\alpha \epsilon_n^{2-5.8\delta} \leq P(A) \leq c' \epsilon_n^{2-6.2\delta} \tag{6.17}
\]
for \(c, c' > 0\) independent of \(n\).

With \(t_{i,n} = 4i \rho_n\) and \(N_n = [(4 \rho_n)^{-1}] = [0.25 \epsilon_n^{-2+5.6\delta}]\), set \(A_i = A \circ \theta_{t_{i,n}}\), that is, the event \(A\) for the shifted path \(W^{t_{i,n}}\) (\(\tilde{W}^{t_{i,n}}\)). By the strong Markov property, for any \(i = 1, \ldots, N_n\),
\[
P(\hat{z}_\infty(W_{t_{i,n}}, \epsilon_n) \geq (1 + \delta)^5 | A_i) \leq 2 \max_{|x_0| \geq \epsilon_n^{-\delta}} P^{x_0}(\inf_{t \geq 0} |W_t| < \epsilon_n) \leq 2 \epsilon_n^{(d-2)\delta},
\]
where (6.14) was used in the second inequality. Hence, by the independence of the events \(\{A_i\}_{i=1}^{N_n}\),
\[
P\left(\min_{i=1}^{N_n} \hat{z}_\infty(W_{t_{i,n}}, \epsilon_n) \geq (1 + \delta)^5 \right)
\leq (1 - P(A))^{N_n} + \sum_{i=1}^{N_n} P(\hat{z}_\infty(W_{t_{i,n}}, \epsilon_n) \geq (1 + \delta)^5 | A_i)
\leq e^{-P(A)N_n} + \sum_{i=1}^{N_n} P(\hat{z}_\infty(W_{t_{i,n}}, \epsilon_n) \geq (1 + \delta)^5 | A_i)P(A_i)
\leq e^{-\alpha \epsilon_n^{-2\delta}} + c' \epsilon_n^{-6\delta} \epsilon_n^{(d-2)\delta}
\leq e^{-\epsilon_n^{-2\delta}} + c' \epsilon_n^{4\delta}
\]
and (6.3) follows by an application of the Borel-Cantelli Lemma. (One can see now the reason for choosing 5.6 above. With more care, we could have chosen any \(5 \leq q < 6\)). This completes the proof of Theorem 1.2. 

\[\square\]
7 Almost sure convergence of exponential moments

Proof of Theorem 1.4: For any Borel function $f: [a, b] \to \mathbb{R}^d$, we use $\mu_{a,b}^f$ to denote its occupation measure:

$$
\mu_{a,b}^f(A) = \int_a^b 1_A(f_t) \, dt
$$

for all Borel set $A \subseteq \mathbb{R}^d$. We use the abbreviations $\mu_T^f = \mu_{0,T}^f$ and $\bar{\mu}_T^f = \mu_{-T,T}^f$.

As a first step in proving Theorem 1.4, we rewrite things so that we deal only with occupation measures of $B(0, 1)$. Writing $W_t^\epsilon = \epsilon^{-1} W_{\epsilon t}$ and $W_{s,t}^\epsilon = W_{t+s}^\epsilon - W_t^\epsilon$ with similar notation for $\bar{W}$ we have

$$
\mu_1^W(B(W_{\epsilon t}, \epsilon)) = \int_0^1 1_{|W_{s,t}^\epsilon - W_{s,t}^\epsilon| \leq \epsilon} \, ds = \epsilon^2 \int_0^{1/\epsilon^2} 1_{|W_{s,t}^\epsilon - W_{s,t}^\epsilon| \leq \epsilon} \, ds = \epsilon^2 \int_0^{1/\epsilon^2} 1_{|W_{s,t}^\epsilon - W_{s,t}^\epsilon| \leq 1} \, ds = \epsilon^2 \int_0^{1/\epsilon^2} 1_{B(0,1)}(W_s^\epsilon - W_t^\epsilon) \, ds
$$

and consequently

$$
\int_0^1 e^{\theta \mu_1^W(B(W_t, \epsilon))/\epsilon^2} \, dt = \epsilon^2 \int_0^{1/\epsilon^2} e^{\theta \mu_1^W(B(W_{s,t}, \epsilon))/\epsilon^2} \, dt = \epsilon^2 \int_0^{1/\epsilon^2} \exp \left( \theta \int_0^{1/\epsilon^2} 1_{B(0,1)}(W_s^\epsilon - W_t^\epsilon) \, ds \right) \, dt \leq \epsilon^2 \int_0^{1/\epsilon^2} \exp \left( \theta \int_{-\infty}^\infty 1_{B(0,1)}(\bar{W}_s^\epsilon - \bar{W}_t^\epsilon) \, ds \right) \, dt = \epsilon^2 \int_0^{1/\epsilon^2} \exp \left( \theta \int_{-\infty}^\infty 1_{B(0,1)}(\bar{W}_s^\epsilon) \, ds \right) \, dt = \epsilon^2 \int_0^{1/\epsilon^2} e^{\theta \bar{\mu}_\epsilon^\epsilon(B(0,1))} \, dt. \tag{7.1}
$$

Hence for each $\theta < q_d^2/2$ and any subsequence $\epsilon_m \to 0$, in order to show that

$$
\limsup_{m \to \infty} \int_0^1 e^{\theta \mu_1^W(B(W_t, \epsilon_m))/\epsilon_m^2} \, dt \leq \mathbb{E} \left( e^{\theta \bar{\mu}_\epsilon^\epsilon(B(0,1))} \right) \quad a.s. \tag{7.2}
$$

it suffices to show that

$$
\lim_{m \to \infty} \epsilon_m^2 \int_0^{1/\epsilon_m^2} e^{\theta \bar{\mu}_\epsilon^\epsilon(B(0,1))} \, dt = \mathbb{E} \left( e^{\theta \bar{\mu}_\epsilon^\epsilon(B(0,1))} \right) \quad a.s. \tag{7.3}
$$

30
For any $1 < p < 2$ such that $p\theta < q_d^2/2$, (7.3) will follow with $\epsilon_m = m^{-2/(p-1)}$ from the Borel-Cantelli lemma, Chebycheff’s inequality and the following lemma.

**Lemma 7.1** For any $\theta < q_d^2/2$, there exists $c = c_{d,\theta}$ finite, such that for all $n$,

$$
\left\| \frac{1}{n^2} \int_0^{n^2} \theta \mu_{n}^{\theta, n^{-1}, t}(B(0,1)) \, dt - \frac{1}{n^2} \int_0^{n^2} \theta \mu_{n}^{\theta, n^{-1}, t}(B(0,1)) \, dt \right\|_1 \leq cn^{-(d/2-1)},
$$

and for any $1 < p < 2$ such that $p\theta < q_d^2/2$, there exists $c = c_{p,d,\theta}$ finite, such that for all $n$,

$$
\left\| \frac{1}{n^2} \int_0^{n^2} \theta \mu_{n}^{\theta, n^{-1}, t}(B(0,1)) \, dt - \mathbb{E}\left(e^{\theta \mu_{n}^{\theta, n^{-1}}(B(0,1))}\right) \right\|_p \leq cn^{-(1-1/p)}.
$$

We next show that for any $1 < p < 2$ such that $p\theta < q_d^2/2$, and with $\epsilon_m = m^{-2/(p-1)}$

$$
\lim_{m \to \infty} \inf \int_0^1 \theta \mu_{n}^{\theta, n^{-1}}(B(W_t, \epsilon_m))/\epsilon_m \, dt \geq \mathbb{E}\left(e^{\theta \mu_{n}^{\theta, n^{-1}}(B(0,1))}\right) \quad a.s.
$$

Note that for any $n \leq t \leq n^2 - n$

$$
\int_0^{n^2} 1_{B(0,1)}(W_s^{n-1} - W_t^{n-1}) \, ds = \int_0^{n^2-t} 1_{B(0,1)}(\tilde{W}_s^{n-1, t}) \, ds \\
\geq \int_{-n}^n 1_{B(0,1)}(\tilde{W}_s^{n-1, t}) \, ds = \tilde{\mu}_n^{\tilde{W}^{-1, t}}(B(0,1)).
$$

Hence from (7.1),

$$
\int_0^1 \theta \mu_{n}^{\theta, n^{-1}}(B(W_t, n^{-1}))/n^2 \, dt \\
\geq \frac{1}{n^2} \int_0^{n^2} \exp \left( \theta \int_0^{n^2} 1_{B(0,1)}(W_s^{n-1} - W_t^{n-1}) \, ds \right) \, dt \\
\geq \frac{1}{n^2} \int_{-n}^n \theta \mu_{n}^{\theta, n^{-1}, t}(B(0,1)) \, dt.
$$

(7.6) then follows by using Lemma 7.1 as before and noting that

$$
\left\| \frac{1}{n^2} \int_0^{n^2} \theta \mu_{n}^{\theta, n^{-1}, t}(B(0,1)) \, dt - \frac{1}{n^2} \int_{-n}^{n^2-n} \theta \mu_{n}^{\theta, n^{-1}, t}(B(0,1)) \, dt \right\|_1 \\
\leq \left\| \frac{2}{n^2} \int_0^{n} \theta \mu_{n}^{\theta, n^{-1}, t}(B(0,1)) \, dt \right\|_1 + \left\| \frac{1}{n^2} \int_{n^2-n}^{n^2} \theta \mu_{n}^{\theta, n^{-1}, t}(B(0,1)) \, dt \right\|_1 \\
\leq \frac{1}{n^2} \int_0^{n} \theta \mu_{n}^{\theta, n^{-1}, t}(B(0,1)) \, dt + \frac{1}{n^2} \int_{n^2-n}^{n^2} \theta \mu_{n}^{\theta, n^{-1}, t}(B(0,1)) \, dt \\
\leq 2n^{-1} \theta \mu_{n}^{\theta, n^{-1}}(B(0,1))_1 \\
\leq 2n^{-1} \theta \mu_{n}^{\theta, n^{-1}}(B(0,1))_1.
$$
Since \( \mu_1^W (B(W_1, \epsilon)) \) is monotone in \( \epsilon \) and \( \lim_{m \to \infty} \epsilon_{m+1}/\epsilon_m = 1 \), the proof of Theorem 1.4 now follows from (7.2), (7.6) and a simple interpolation argument.

**Proof of Lemma 7.1:** (7.4) will follow from

\[
\| \frac{1}{n^2} \int_0^{n^2} e^{\theta \bar{p}_{n}^{\bar{W}^{-1},t} (B(0,1))} dt - \frac{1}{n^2} \int_0^{n^2} e^{\theta \bar{p}_{n}^{\bar{W}^{-1},t} (B(0,1))} dt \|_1 \leq \frac{1}{n^2} \int_0^{n^2} \| e^{\theta \bar{p}_{n}^{W^{-1},t} (B(0,1))} - e^{\theta \bar{p}_{n}^{W^{-1},t} (B(0,1))} \|_1 dt
\]

and the following lemma.

**Lemma 7.2** For any \( \theta < \frac{q_2^2}{2} \), there exists \( c = c_{d, \theta} \) finite such that for any \( \epsilon > 0 \),

\[
\| e^{\theta \bar{p}_{n}^{\bar{W}}} (B(0,1)) - e^{\theta \bar{p}_{n}^{\bar{W}} (B(0,1))} \|_1 \leq c \epsilon^{d/2 - 1}.
\]

As for (7.5), we first rewrite

\[
\frac{1}{n^2} \int_0^{n^2} e^{\theta \bar{p}_{n}^{\bar{W}^{-1},t} (B(0,1))} dt = \frac{1}{n} \sum_{k=0}^{n-1} \frac{1}{n} \int_0^{(k+1)n} e^{\theta \bar{p}_{n}^{\bar{W}^{-1},t} (B(0,1))} dt
\]

where

\[
I_{n,k} = \frac{1}{n} \int_0^{(k+1)n} e^{\theta \bar{p}_{n}^{\bar{W}^{-1},t} (B(0,1))} dt.
\]

Unraveling the definitions we see that for each fixed \( n \), the \( I_{n,k} ; 0 \leq k \leq n \) are identically distributed, and \( I_{n,k} \) is measurable with respect to the \( \sigma \)-algebra generated by \( \{\bar{W}_{t+s}^{n-1} - \bar{W}_{t}^{n-1} ; kn \leq t \leq (k+1)n; -n \leq s \leq n\} \). Hence \( I_{n,k} \) and \( I_{n,k'} \) are independent as soon as \( |k - k'| \geq 3 \). Thus we can write

\[
\frac{1}{n} \sum_{k=0}^{n} I_{n,k} = \frac{1}{n} \sum_{k=0}^{n/3} I_{n,3k} + \frac{1}{n} \sum_{k=0}^{n/3} I_{n,1+3k} + \frac{1}{n} \sum_{k=0}^{n/3} I_{n,2+3k}
\]

where each of the three sums on the right hand side is now a sum of i.i.d. random variables. Furthermore

\[
\mathbb{E} (I_{n,k}) = \frac{1}{n} \int_0^{(k+1)n} \mathbb{E} \left( e^{\theta \bar{p}_{n}^{\bar{W}^{-1},t} (B(0,1))} \right) dt = \mathbb{E} \left( e^{\theta \bar{p}_{n}^{W} (B(0,1))} \right).
\]

32
Using Lemma 7.2, to complete the proof of Lemma 7.1 it now suffices to note that for any $1 < p < 2$ such that $p \theta < q_d^2/2$ we have the following bounds, where the first inequality comes from the Marcinkiewicz-Zygmund inequality (see for example [24, Pg. 341], where our condition $p \theta < q_d^2/2$ guarantees that $I_n,k \in L^p$), and the second inequality comes from the fact that $|a + b|^p/2 \leq |a|^p/2 + |b|^p/2$ (since $p < 2$):

$$
\mathbb{E} \left( \frac{1}{n^{3/2}} \sum_{k=0}^{n/3} (I_n,i+3k - \mathbb{E}(I_n,i+3k))^p \right) \leq \frac{c}{n^p} \mathbb{E} \left( \sum_{k=0}^{n/3} (I_n,i+3k - \mathbb{E}(I_n,i+3k))^2 \right)^{p/2} \leq c n^{-(p-1)}$

for $i = 0, 1, 2$.

**Proof of Lemma 7.2**: Let $p_r(x) = (2\pi r)^{-d/2} \exp(-|x|^2/2r)$ and $u^0(x) = \int_0^\infty p_r(x) dr = \frac{c}{|x|^{d-2}}$ denote the zero-potential of $W_i$. Let $\Lambda_d$ denote the norm of

$$
Kf(x) = \int_{B(0,1)} u^0(x-y)f(y) dy
$$

considered as an operator from $L^2(B(0,1), dx)$ to itself, observing that $\Lambda_d^{-1} = q_d^2/2$ is the first eigenvalue of the half-Laplacian in the unit ball of $\mathbb{R}^{d-2}$ with Dirichlet boundary conditions.

While $u^0 \notin L^2(B(0,1), dx)$ for $d > 3$, we always have $u^0 \in L^1(B(0,1), dx)$, hence $K^i u^0 \in L^1(B(0,1), dx)$ for all $i$. Further, each application of $K$ lowers the degree of divergence by 2, so that $K^i u^0 \in L^2(B(0,1), dx)$ for sufficiently large $i$, ($i = [d/2]$ will do). In particular, for some $\kappa_d < \infty$ and all $i$

$$
\int_{B(0,1)} K^i u^0(x) dx \leq \kappa_d (\Lambda_d)^i. \quad (7.7)
$$

Set $t_0 = 0, x_0 = 0$, we first bound the following moments for $m = 1, 2, \ldots$

$$
\frac{1}{m!} \mathbb{E} \left( \int_1^\infty 1_{B(0,1)}(W_r) dr \{ \int_0^\infty 1_{B(0,1)}(W_s) ds \}^{m-1} \right) = \frac{1}{m} \sum_{i=1}^m \int_{B(0,1)}^{m} \int_{t_{j-1}}^{t_j} \prod_{j=1}^m p_{t_j-t_{j-1}}(x_j-x_{j-1}) dt_1 \cdots dt_m dx_1 \cdots dx_m
$$

\begin{align*}
&= \frac{1}{m} \sum_{i=1}^m \int_{B(0,1)}^{m} \int_{t_{j-1}}^{t_j} \prod_{j=1}^m p_{r_j}(x_j-x_{j-1}) dr_1 \cdots dr_m dx_1 \cdots dx_m
\end{align*}

33
\begin{align*}
& \leq \sum_{i=1}^{m} \int_{B(0,1)^m} \prod_{j=1}^{m} pr_j(x_j - x_{j-1}) \ dr_1 \cdots \ dr_m \ dx_1 \cdots \ dx_m \\
& = \sum_{i=1}^{m} \int_{B(0,1)^m} \prod_{j=1,j\neq i}^{m} u^0(x_j - x_{j-1}) \int_{(m)_{i-1}}^{\infty} pr_i(x_i - x_{i-1}) \ dr_i \ dx_1 \cdots \ dx_m \\
& \leq \left( \int_{(m)_{i-1}}^{\infty} pr_i(0) \ dr_i \right) \sum_{i=1}^{m} \int_{B(0,1)^m} \prod_{j=1,j\neq i}^{m} u^0(x_j - x_{j-1}) \ dx_1 \cdots \ dx_m \\
& = k_d(m) \frac{d/2-1}{m^{d/2} A_d m^{1}} ,
\end{align*}

where \((\cdot, \cdot)_{B(0,1)}\) denotes the inner product in \(L^2(B(0,1), dx)\) and (7.7) was used in the last inequality. With \(c_d\) independent of \(m\) and \(g_{d, \theta} = \mathbb{E}(e^{\theta \mu^W_{\infty}(B(0,1))})\) finite, it follows that

\[
\| e^{\theta \mu^W_{\infty}(B(0,1))} - e^{\theta \mu^W_{1/\epsilon}(B(0,1))} \|_1
\]

\[
= \mathbb{E} \left( e^{\theta \mu^W_{\infty}(B(0,1))} \right) - \mathbb{E} \left( e^{\theta \mu^W_{1/\epsilon}(B(0,1))} \right)
\]

\[
= \left\{ \mathbb{E} \left( e^{\theta \mu^W_{\infty}(B(0,1))} \right) \right\}^2 - \left\{ \mathbb{E} \left( e^{\theta \mu^W_{1/\epsilon}(B(0,1))} \right) \right\}^2
\]

\[
\leq 2 g_{d, \theta} \left| \mathbb{E} \left( e^{\theta \mu^W_{\infty}(B(0,1))} \right) - \mathbb{E} \left( e^{\theta \mu^W_{1/\epsilon}(B(0,1))} \right) \right|
\]

\[
\leq 2 g_{d, \theta} \mathbb{E} \left( \mu^W_{\infty}(B(0,1)) - \mu^W_{1/\epsilon}(B(0,1)) \right) \mathbb{E}(e^{\theta \mu^W_{\infty}(B(0,1))})
\]

\[
= 2 g_{d, \theta} \sum_{m=0}^{\infty} \frac{\theta^{m+1}}{m!} \mathbb{E} \left( \int_{1/\epsilon}^{\infty} 1_{B(0,1)}(W_r) \ dr \int_{0}^{\infty} 1_{B(0,1)}(W_s) \ ds \right)^m
\]

\[
\leq 2 g_{d, \theta} c_d \theta^{d/2-1} \sum_{m=0}^{\infty} \frac{\theta^{m+1}}{m!} \leq c_d \theta^{d/2-1}
\]

for any \(\theta < \Lambda_d^{-1}\), as needed to complete the proof of Lemma 7.2 and hence of Theorem 1.4. \(\square\)

8 The coarse multifractal spectrum

Proof of Corollary 1.5: The upper bound in Corollary 1.5 is an immediate consequence of (1.10) and Chebycheff’s inequality. Turning to the corresponding lower bound, fix \(a \in (0, 2/\theta^*)\).
Choosing $\delta \in (0, 1/4)$ such that $\eta = 2 - a\theta^*(1 + 3\delta) > 0$ and $\epsilon_n$ as in (5.2), leads (see (6.1)) to
\[
\liminf_{\epsilon \to 0} \frac{\log \mathcal{L}e b\{0 \leq t \leq 1 \mid z_1(W_t, \epsilon) \geq a\}}{\log \epsilon} \geq \liminf_{n \to \infty} \frac{\log \mathcal{L}e b\{0 \leq t \leq 1 \mid z_1(W_t, \epsilon_n) \geq \frac{a}{1-\eta}\}}{\log \epsilon_{n-1}}.
\]  
(8.1)

Let $W^t_i = W_{i+s} - W_i$, $\delta_n = \frac{c_2}{\log \epsilon_n}6$ and $\beta_n = 1 - 2\log \epsilon_n^{-2}$. The random variables $Y^{(n)}_i = \mu_1^W\delta_n(B(0, \beta_n \epsilon_n))/h(\epsilon_n)$, $i = 1, \ldots, \delta_n^{-1} - 1$ are i.i.d. The Localization Lemma implies that for some $c > 0$ and all $n$ large enough,
\[
p_n^* := \mathbb{P}(Y^{(n)} \geq a/(1 - \delta)) \geq c\epsilon_n^{a\theta^*(1+2\delta)}.
\]

Thus, by standard tail estimates for the Binomial($\delta_n^{-1} - 1, p_n^*$), for all $n$ large enough,
\[
\mathbb{P}(|\{i : Y^{(n)}_i \geq a/(1 - \delta)\}| \leq \epsilon_n^{-\eta}) \leq \exp(-\epsilon_n^{-\eta})
\]

since $(1 - \delta)^{-1} \leq 1 + 2\delta$. It follows that a.s., for all $n \geq n_0(\omega, \delta, a)$,
\[
\{|i : Y^{(n)}_i \geq a/(1 - \delta)| \geq \epsilon_n^{-\eta}\}.
\]  
(8.2)

Taking $\rho_n = c_2/\log \epsilon_n^{-6}$, by Lévy’s uniform modulus of continuity, we have that a.s. for some $n_1 = n_1(\omega) < \infty$ and all $n \geq n_1$,
\[
\delta_n^{-1} \sup_{|s| < \rho_n} W_{\delta_n+s} - W_{\delta_n} < (1 - \beta_n)\epsilon_n
\]

which together with (8.2) implies that a.s. for any $n \geq n_2(\omega, \delta, a)$,
\[
\mathcal{L}e b\{0 \leq t \leq 1 \mid z_1(W_t, \epsilon_n) \geq a/(1 - \delta)\} \geq \rho_n|\{i : Y^{(n)}_i \geq a/(1 - \delta)\}| \geq \epsilon_n^{2-\eta+\delta}.
\]

In view of (8.1), we have a.s.
\[
\liminf_{\epsilon \to 0} \frac{\log \mathcal{L}e b\{0 \leq t \leq 1 \mid z_1(W_t, \epsilon) \geq a\}}{\log \epsilon} \geq (1 - 2\delta)^{-1/2}(2 - \eta - \delta).
\]

To complete the proof, consider $\delta \downarrow 0$, for which $2 - \eta - \delta \to a\theta^*$.  \qed

35
9 Large occupation measure at all scales

Proof of Theorem 1.6: For $k \in (1, \infty)$, $T < \infty$, let $\Gamma_k = \{ x : |x| \in [1/k, k] \}$ and

$$D_a := \{ x \in \Gamma_k | \liminf_{\epsilon \to 0} \frac{\mu^W_T(B(x, \epsilon))}{\epsilon^2} \geq a \}.$$  

(We work with the annulus $\Gamma_k$ rather than the ball $B(0,k)$ because the basic bound we will use, Lemma 9.2, blows up at the origin).

Fix $\delta > 0$ and let $b = 1 + \delta > 1$. Set $\eta_n = 2^{-n}$ and $\delta_n = \eta_n^{1-\delta}$. Let $\{x_j : j = 1, \ldots, K_n\}$, $K_n \leq c(\delta, k, d) \eta_n^{-d}$, denote a maximal collection of points in $\Gamma_k$ such that $\inf_{\ell \neq j} |x_\ell - x_j| \geq \delta \eta_n$. Let $\mathcal{H}_n = \mathcal{H}_n(a, \delta, T)$ be the set of $j$, $1 \leq j \leq K_n$, such that

$$\inf_{\epsilon \in [\eta_n, \delta_n]} \frac{\mu^W_T(B(x_j, \epsilon))}{\epsilon^2} \geq \frac{a}{b}. \quad (9.1)$$

We will shortly prove that for any $\gamma > 0$ we can find $\delta > 0$ such that for some $c = c(\alpha, \delta, T) < \infty$ and all $n$,

$$\mathbb{E}|\mathcal{H}_n| \leq c \eta_n^{L_\alpha} \quad (9.2)$$

where $I_d(v)$ is defined in (1.12). Assuming this for the moment, let $U_{n,j} = B(x_j, \delta \eta_n)$. Then, for any $x \in \Gamma_k$ there exists $j \in \{1, \ldots, K_n\}$ such that $x \in U_{n,j}$ and $B(x, \epsilon) \subseteq B(x_j, \epsilon + \delta \eta_n) \subseteq B(x_j, \epsilon b)$ for all $\epsilon \geq \eta_n$. If $x \in D_a$ then a.s. for some $m_1(\omega, x, b) < \infty$ and all $n \geq m_1$,

$$\inf_{\epsilon \in [\eta_n, \delta_n]} \frac{\mu^W_T(B(x, \epsilon))}{\epsilon^2} \geq \frac{a}{b}.$$  

Therefore, $\bigcup_{m \geq m_1} \mathcal{U}_{n,j}$ forms a $2\delta \eta_m$-cover of $D_a$ for any $m \geq 1$. Since $U_{n,j}$ has diameter $2\delta \eta_n$, it follows from (9.2) that

$$\mathbb{E} \sum_{n=m}^{\infty} \sum_{j \in \mathcal{H}_n} |\mathcal{U}_{n,j}|^{2-L_\alpha + 2\gamma} = \sum_{n=m}^{\infty} \mathbb{E}|\mathcal{H}_n|(2\delta \eta_n)^{2-L_\alpha + 2\gamma} \leq c \sum_{n=m}^{\infty} \eta_n^\gamma < \infty. \quad (9.3)$$

Thus, $\sum_{n=m}^{\infty} \sum_{j \in \mathcal{H}_n} |\mathcal{U}_{n,j}|^{2-L_\alpha + 2\gamma}$ is finite a.s. implying that $\dim(D_a) \leq 2 - L_\alpha + 2\gamma$ a.s. for any $T < \infty$, $\gamma > 0$. Since a.s. there exists $T_k = T_k(\omega)$ finite, such that $|W_t| \geq (k + 1)$ for any $t \geq T_k$, obviously a.s. also

$$\dim(\{ x \in \Gamma_k | \liminf_{\epsilon \to 0} \frac{\mu^W_\infty(B(x, \epsilon))}{\epsilon^2} \geq a \}) \leq 2 - L_\alpha + 2\gamma.$$  

36
Taking $\gamma \downarrow 0$ and considering the countable union over $k = 1, 2 \ldots$ completes the proof of (1.14).

To get our upper bound on packing dimension, denote by $D^m(a/b)$ the set of points $x \in \mathbb{R}^d$ such that for all $n \geq m$, we have

$$\inf_{\epsilon \in [\eta_n, \delta_n]} \frac{\mu^W_T(B(x, \epsilon))}{\epsilon^2} \geq \frac{a}{b}.$$ 

Clearly, $\bigcup_{j \in \mathcal{H}_n} \mathcal{U}_{n,j}$ forms a $2\delta \eta_n$-cover of $D^m(a/b)$ for any $n \geq m$. Thus, from (9.3)

$$\lim_{n \to \infty} \sum_{j \in \mathcal{H}_n} |\mathcal{U}_{n,j}|^{2-I_d(a)+2\gamma} = 0 \quad \text{a.s.} \quad (9.4)$$

Denote by $\mathcal{N}(A, \epsilon)$ the minimal cardinality of a collection of balls of radius $\epsilon$ that covers $A$. Recall that $\overline{\dim}_M(A)$, the upper Minkowski dimension of a set $A$ (also known as the upper box-counting dimension), may be defined by

$$\overline{\dim}_M(A) = \limsup_{\epsilon \to 0} \frac{\log \mathcal{N}(A, \epsilon)}{|\log \epsilon|}; \quad (9.5)$$

see [6, (3.5)]. From (9.4) we may deduce that $\overline{\dim}_M(D^m(a/b)) \leq 2 - I_d(a) + 2\gamma$. Since $b > 1$, necessarily

$$D_a \subset \bigcup_{m \geq 1} D^m(a/b), \quad (9.6)$$

and the upper bound $\dim_p(D_a) \leq 2 - I_d(a) + 2\gamma$ a.s. follows by [6, Prop. 3.8]. This completes the proof of (1.15).

We next recall that $I_d(v)$ of (1.12) is strictly increasing in $v \geq 2/(d-2)$, whereas $I_d(C_d) = 2$. Hence, fixing $a > C_d$, we may and shall fix $\gamma > 0$ such that $I_d(a) \geq 2 - \gamma > 0$. Then, by (9.2), for any $\delta > 0$ sufficiently small

$$\sum_{n=1}^{\infty} \mathbb{P}(|\mathcal{H}_n| \geq 1) \leq \sum_{n=1}^{\infty} \mathbb{E}|\mathcal{H}_n| \leq c_1 \sum_{n=1}^{\infty} \eta_n^{I_d(a)-2} < \infty.$$ 

Thus, by Borel-Cantelli, it follows that a.s. $\mathcal{H}_n$ is empty for all $n \geq m_2(\omega)$, implying that the sets $D_a$ are a.s. empty for all $T < \infty$. Since a.s.

$$\liminf_{\epsilon \to 0} \frac{\mu^W_T(B(0, \epsilon))}{\epsilon^2} = 0$$

37
(see [28, Theorem 6.8]), taking \( k \uparrow \infty \) and \( a \downarrow C_d \) completes the proof of (1.16) and hence of Theorem 1.6, subject only to (9.2).

The first step in the proof of (9.2) is the following simple lemma (see [21] for the definition and properties of Bessel processes).

**Lemma 9.1** Let \( Z = \int_0^T U_s^{-2} ds \) with \( \{ U_s : s \in [0,T] \} \) the Bessel process of index \( d' = d/2 - 1 > 0 \), starting at \( U_0 = u \in (0,k] \). Then, for any \( \alpha \in (0,d'], b > 1 \), there exist \( c = c(b,T,d',k) < \infty \) such that

\[
\mathbb{E}^u_{(d')} \left( e^{(d'^2/2-\alpha^2/2)} Z 1_{\inf_{s \in [0,T]} U_s \leq v} \right) \leq c v^{2\alpha/b} u^{-(d'-\alpha)-2\alpha/b} .
\]

**Proof:** Let \( P_{(\nu)}^u (\cdot) \) denote the law of the Bessel process \( \{ U_s : s \in [0,T] \} \) of index \( \nu > 0 \) starting at \( U_0 = u \). Recall that for any index \( \nu > 0 \),

\[
dU_s = (\nu + 1/2) \frac{ds}{U_s} + dB_s , \quad U_0 = u > 0 ,
\]

where \( B_s \) is a one dimensional Brownian motion. In particular, \( dP_{(\nu)}^u / dP_{(\alpha)}^u \) exists for any \( d' \geq \alpha > 0 \) and is given by the Girsanov transformation as (see [21, Pg. 419]),

\[
\frac{dP_{(\nu)}^u}{dP_{(\alpha)}^u} = \left( \frac{U_T}{u} \right)^{d'-\alpha} e^{-\left( d'^2/2 - \alpha^2/2 \right) \int_0^T U_s^{-2} ds} .
\]

In particular, by Hölder’s inequality, for \( q = b/(b-1) \),

\[
\mathbb{E}^u_{(d')} \left( e^{(d'^2/2-\alpha^2/2)} Z 1_{\inf_{s \in [0,T]} U_s \leq v} \right) = u^{a-d'} \mathbb{E}^u_{(\alpha)} \left( U_T^{d'-\alpha} 1_{\inf_{s \geq 0} U_s \leq v} \right)^{1/q} \leq u^{a-d'} \mathbb{E}^u_{(\alpha)} \left( U_T^{q(d'-\alpha)} \right)^{1/q} \leq u^{a-d'} \left( \frac{v}{u} \right)^{2\alpha/b} \mathbb{E}^k_{(\alpha)} \left( U_T^{q(d'-\alpha)} \right)^{1/q}
\]

where the last inequality follows using the fact that the Bessel process of index \( \alpha \) has scale function \( -x^{-2\alpha} \) [21, Pg. 415], and for the right-most expectation we used a simple comparison argument. A further comparison argument shows that we can take \( c = \mathbb{E}^u_{(d')} ((1 \lor U_T)^{q d'})^{1/q} < \infty \).

The next step in proving (9.2) is to establish the following consequence of Lemma 9.1.
Lemma 9.2: For any $T < \infty$, $b > 1$, $k > 1$, there exists $c < \infty$ such that for any $a > 0$, $\alpha \in (0, d')$, $\eta > 0$, $\delta = \eta^{1-b^{-1}}$, $|x| \in (0, k]$,

$$
P\left( \inf_{e \in [\eta, \delta]} \frac{\mu_T^W(B(x, b e))}{e^2} \geq \frac{a}{b} \right) \leq c \eta^{ab^{-4}(d'' - \alpha^2) + 2a/b |x| - (d - \alpha) - 2a/b}. \tag{9.8}
$$

Proof: Fix $T, a, b, k, \alpha, \eta, \delta$ and $x$ as in the statement of the lemma. Observe that $U_s = |W_s - x|$ is a Bessel process of index $d'$, starting at $U_0 = |x| \in (0, k]$. Clearly

$$
\{\mu_T^W(B(x, v)) > 0\} = \{ \inf_{s \in [0, T]} U_s < v \} \tag{9.9}
$$

Setting $Z = \int_0^T U_s^{-2} ds$, also

$$
b^2 Z = \int_0^T \int_{b^{-1} U_s} 2de \frac{2de}{e^3} ds = \int_0^T \int_{\{W_s - x \leq be\}} \frac{2de}{e^3} ds
$$

$$
= \int_0^\infty \frac{2de}{e^3} \mu_T^W(B(x, be)) \geq \int_\eta^\delta \frac{2de}{e^3} \mu_T^W(B(x, be)). \tag{9.10}
$$

If

$$
\inf_{e \in [\eta, \delta]} e^{-2} \mu_T^W(B(x, be)) \geq \frac{a}{b}
$$

then $\mu_T^W(B(x, b\eta)) > 0$ and

$$
\int_\eta^\delta \frac{2de}{e^3} \mu_T^W(B(x, be)) \geq \frac{a}{b} \int_\eta^\delta \frac{2de}{e} = -2ab^{-2} \log \eta.
$$

Thus, for $v = b\eta$ and $\lambda = \langle d'' - \alpha^2 \rangle \geq 0$, by (9.9), (9.10) and Chebychev’s inequality,

$$
P\left( \inf_{e \in [\eta, \delta]} \frac{\mu_T^W(B(x, b e))}{e^2} \geq \frac{a}{b} \right) \leq P_{(d')}(Z \geq -2ab^{-2} \log \eta, \inf_{s \in [0, T]} U_s \leq v)
$$

$$
\leq \eta^{2\lambda ab^{-4}} E_{(d')}[e^{\lambda Z}] \mathbf{1}_{\inf_{s \in [0, T]} U_s \leq v].
$$

We thus obtain (9.8) by applying Lemma 9.1. \hfill \square

We now return to complete the proof of (9.2). For $b > 1$ and $\alpha \in (0, d']$ let

$$
f_a(b, \alpha) = ab^{-4}(d'' - \alpha^2) - d + 2a/b.
$$
By Lemma 9.2, for some \(c,c_1,c_2 < \infty\) independent of \(n\),
\[
\mathbb{E}[\mathcal{H}_n] = \sum_{j=1}^{K_n} \mathbf{P}\left( \inf_{c \in [\eta_n, \delta_n]} \frac{\mu_T(B(x_j, b))}{c^2} \geq \frac{a}{b} \right)
\leq c_{\eta_n}^{ab^{-4}(d^2 - \alpha^2) + 2\alpha/b} \sum_{j=1}^{K_n} |x_j|^{-(d' - \alpha) - 2\alpha/b} \leq c_{\eta_n}^{ab^{-4}(d^2 - \alpha^2) + 2\alpha/b - \delta} \left(1 + \int_{\{|x| \leq k\}} |x|^{-(d' - \alpha) - 2\alpha/b} \, dx\right) \leq c_{\eta_n}^{f_a(b, \alpha)} ,
\]
(9.11)
using \((d' - \alpha) + 2\alpha/b < d' + \alpha \leq d - 1\).

Setting \(\alpha = d' - \theta\) for \(\theta \in [0, d']\), in which case \(d^2 - \alpha^2 = \theta(d - 2 - \theta)\), we see that
\[
f_a(b, \alpha) = ab^{-4}\theta(d - 2 - \theta) - d(1 - b^{-1}) - (2\theta + 2)/b .
\]
(9.12)

Observe that \(I_d(a)\), defined in (1.12), can also be written as
\[
(max\{0, a(d - 2) - 2\})^2/4a ,
\]
whence
\[
I_d(a) = \sup_{0 \leq \theta < (d - 2)/2} \{a\theta(d - 2 - \theta) - 2\theta\} ,
\]
(9.13)
and the supremum in (9.13) is attained at \(\theta = \max\{0, (d - 2)/2 - a^{-1}\}\). Comparing this with (9.12) we see that
\[
\lim_{b \downarrow 1} \sup_{a \in (0, d'] \} f_a(b, \alpha) = I_d(a) - 2
\]
(9.14)
which completes the proof of (9.2) and hence of Theorem 1.6. \(\Box\)

Some unsolved problems:

1. Determine exactly the dimension appearing in (1.14) and the precise asymptotics in (1.16).

2. Does the set considered in (1.14) have equal Hausdorff and packing dimensions?
3. By arguments similar to those in the proof of (1.16), we can show that there exist non-random constants \( \tilde{c}_d > 0, \tilde{C}_d < \infty \) such that

\[
\tilde{c}_d \leq \inf_{t \in [0,1]} \limsup_{\epsilon \to 0} \frac{\mu_W(B(W_t, \epsilon))}{\epsilon^2} \leq \tilde{C}_d \quad \text{a.s.} \tag{9.15}
\]

More precisely, the upper bound here is proved just like the lower bound in (1.16), while the lower bound can be inferred from Perkins [16] or from a branching process argument. As in (1.16), it is an open problem to determine the optimal constants in (9.15).

Acknowledgements We thank N.-R. Shieh and S. J. Taylor for useful discussions and for providing us with a preprint of [23], and J. Pitman for a useful discussion of the Ciesielski-Taylor identity. We are indebted to MSRI, to the organizers of the program on stochastic analysis there, and in particular to S. Evans and R. Williams, for making our collaboration possible.
